

## 12MHz Rail-to-Rail Buffers + 100mA $V_{COM}$ Amplifier

The EL5224, EL5324, and EL5424 feature 8, 10, and 12 low power buffers, respectively, and one high power output amplifier. They are designed primarily for buffering column driver reference voltages in TFT-LCD applications as well as generation of the  $V_{COM}$  supply. Each low power buffer features a -3dB bandwidth of 12MHz and features rail-to-rail input/output capability. The high power buffer can drive 100mA and swings to within 2V of each rail.

The 8-channel EL5224 is available in 24-pin QFN and 24-pin HTSSOP packages, the 10-channel EL5324 is available in 32-pin QFN and 28-pin HTSSOP packages, and the 12-channel EL5424 is available in the 32-pin QFN package. They are specified for operation over the full -40°C to +85°C temperature range.

## Features

- 8, 10, and 12 channel versions
- 12MHz -3dB buffer bandwidth
- 150mA  $V_{COM}$  buffer
- Operating supply voltage from 4.5V to 16.5V
- Low supply current - 6mA total (8-channel version)
- Rail-to-rail input/output swing (buffers only)
- QFN package - just 0.9mm high
- Pb-Free available (RoHS compliant)

## Applications

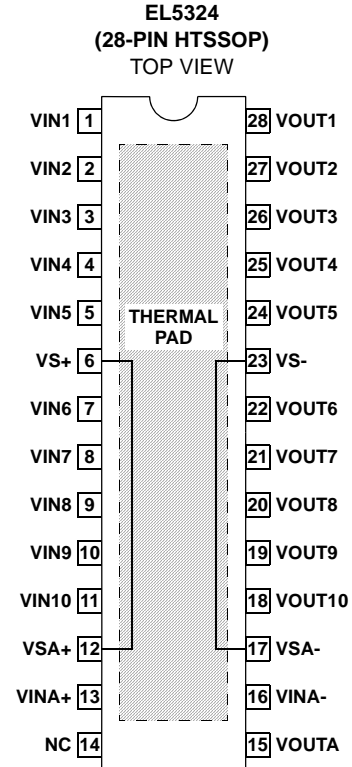

- TFT-LCD column driver buffering and  $V_{COM}$  supply
- Electronics notebooks
- Computer monitors
- Electronics games
- Touch-screen displays
- Portable instrumentation

Applications Information

Product Description

The EL5224, EL5324, and EL5424 unity gain buffers and 100mA  $V_{COM}$  amplifier are fabricated using a high voltage CMOS process. The buffers exhibit rail-to-rail input and output capability and has low power consumption (600 $\mu$ A per buffer). When driving a load of 10k $\Omega$  and 12pF, the buffers have a -3dB bandwidth of 12MHz and exhibits 18V/ $\mu$ s slew rate. The  $V_{COM}$  amplifier exhibits rail-to-rail input. The output can be driving to within 2V of each supply rail. With a 1 $\mu$ F capacitance load, the GBWP is about 1MHz.

Correct operation is guaranteed for a supply range of 4.5V to 16.5V.

The Use of the Buffers

The output swings of the buffers typically extend to within 100mV of positive and negative supply rails with load currents of 5mA. Decreasing load currents will extend the output voltage range even closer to the supply rails. Figure 21 shows the input and output waveforms for the device. Operation is from  $\pm$ 5V supply with a 10k $\Omega$  load connected to GND. The input is a 10V $_{P-P}$  sinusoid. The output voltage is approximately 9.985V $_{P-P}$ .

FIGURE 21. OPERATION WITH RAIL-TO-RAIL INPUT AND OUTPUT

SHORT-CIRCUIT CURRENT LIMIT

The buffers will limit the short circuit current to  $\pm$ 120mA if the output is directly shorted to the positive or the negative supply. If an output is shorted indefinitely, the power dissipation could easily increase such that the device may be damaged. Maximum reliability is maintained if the output continuous current never exceeds  $\pm$ 30mA. This limit is set by the design of the internal metal interconnects.

OUTPUT PHASE REVERSAL

The buffers are immune to phase reversal as long as the input voltage is limited from  $V_S - 0.5V$  to  $V_S + 0.5V$ . Figure 22 shows a photo of the output of the device with the input voltage driven beyond the supply rails. Although the device's output will not change phase, the input's overvoltage should be avoided. If an input voltage exceeds supply voltage by more than 0.6V, electrostatic protection diodes placed in the input stage of the device begin to conduct and overvoltage damage could occur.

FIGURE 22. OPERATION WITH BEYOND-THE-RAILS INPUT

**UNUSED BUFFERS**

It is recommended that any unused buffers have their inputs tied to the ground plane.

**DRIVING CAPACITIVE LOADS**

The buffers can drive a wide range of capacitive loads. As load capacitance increases, however, the -3dB bandwidth of the device will decrease and the peaking increase. The buffers drive 10pF loads in parallel with 10kΩ with just 1.5dB of peaking, and 100pF with 6.4dB of peaking. If less peaking is desired in these applications, a small series resistor (usually between 5Ω and 50Ω) can be placed in series with the output. However, this will obviously reduce the gain slightly. Another method of reducing peaking is to add a snubber circuit at the output. A snubber is a shunt load consisting of a resistor in series with a capacitor. Values of 150Ω and 10nF are typical. The advantage of a snubber is that it does not draw any DC load current or reduce the gain.

**The Use of VCOM Amplifier**

The VCOM amplifier is designed to control the voltage on the back plate of an LCD display. This plate is capacitively coupled to the pixel drive voltage which alternately cycles positive and negative at the line rate for the display. Thus the amplifier must be capable of sourcing and sinking capacitive pulses of current, which can occasionally be quite large (a few 100mA for typical applications).

A simple use of the VCOM amplifier is as a voltage follower, as illustrated in Figure 23. Here, a voltage, corresponding to the mid-DAC potential, is generated by a resistive divider and buffered by the amplifier. The amplifier's stability is designed to be dominated by the load capacitance, thus for very short duration pulses (< 1µs) the output capacitor supplies the current. For longer pulses the VCOM amplifier supplies the current. By virtue of its high transconductance which progressively increases as more current is drawn, it can maintain regulation within 5mV as currents up to 100mA are drawn, while consuming only 2mA of quiescent current.

FIGURE 23. VCOM USED AS A VOLTAGE BUFFER

Alternatively, the back plate potential can be generated by a DAC and the VCOM amplifier used to buffer the DAC voltage, with gain if necessary. This is shown in Figure 24. In this case, the effective transconductance of the feedback is reduced, thus the amplifier will be more stable, but regulation will be degraded by the feedback factor.

FIGURE 24. VCOM USED AS A BUFFER WITH GAIN

**CHOICE OF OUTPUT CAPACITOR**

A 1µF ceramic capacitor with low ESR is recommended for this amplifier. (For example, GRM42\_6X7R105K16). This capacitor determines the stability of the amplifier. Reducing it will make the amplifier less stable, and should be avoided. With a 1µF capacitor, the unity gain bandwidth of the amplifier is close to 1MHz when reasonable currents are being drawn. (For lower load currents, the gain and hence bandwidth progressively decreases.) This means the active trans-conductance is:

$$2\pi \times 1\mu\text{F} \times 1\text{MHz} = 6.28\text{S}$$

This high transconductance indicates why it is important to have a low ESR capacitor.

If:

$$\text{ESR} \times 6.28 > 1$$

then the capacitor will not force the gain to roll off below unity, and subsequent poles can affect stability. The recommended capacitor has an ESR of 10mΩ, but to this must be added the resistance of the board trace between the capacitor and the sense connection - therefore this should be kept short, as illustrated in Figure 21, by the diagonal line to the capacitor. Also ground resistance between the capacitor and the base of R2 must be kept to a minimum. These constraints should be considered when laying out the PCB.

If the capacitor is increased above 1µF, stability is generally improved and short pulses of current will cause a smaller “perturbation” on the V<sub>COM</sub> voltage. The speed of response of the amplifier is however degraded as its bandwidth is decreased. At capacitor values around 10µF, a subtle interaction with internal DC gain boost circuitry will decrease the phase margin and may give rise to some overshoot in the response. The amplifier will remain stable though.

### RESPONSE TO HIGH CURRENT SPIKES

The V<sub>COM</sub> amplifier's output current is limited to 150mA. This limit level, which is roughly the same for sourcing and sinking, is included to maintain reliable operation of the part. It does not necessarily prevent a large temperature rise if the current is maintained. (In this case the whole chip may be shut down by the thermal trip to protect functionality.) If the display occasionally demands current pulses higher than this limit, the reservoir capacitor will provide the excess and the amplifier will top the reservoir capacitor back up once the pulse has stopped. This will happen on the µs time scale in practical systems and for pulses 2 or 3 times the current limit, the V<sub>COM</sub> voltage will have settled again before the next line is processed.

### Power Dissipation

With the high-output drive capability of the EL5224, EL5324, and EL5424 buffer, it is possible to exceed the 125°C “absolute-maximum junction temperature” under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if load conditions need to be modified for the buffer to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$P_{DMAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

where:

- T<sub>JMAX</sub> = Maximum junction temperature
- T<sub>AMAX</sub> = Maximum ambient temperature
- θ<sub>JA</sub> = Thermal resistance of the package
- P<sub>DMAX</sub> = Maximum power dissipation in the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the loads, or:

$$P_{DMAX} = \sum i \times [V_S \times I_{SMAX} + (V_{S+} - V_{OUT}^i) \times I_{LOAD}^i] + [V_{SA} \times I_{SAA} + (V_{SA+} - V_{OUTA}) \times I_{LA}]$$

when sourcing, and:

$$P_{DMAX} = \sum i \times [V_S \times I_{SMAX} + (V_{OUT}^i - V_{S-}) \times I_{LOAD}^i] + [V_{SA} \times I_{SAA} + (V_{SA+} - V_{OUTA}) \times I_{LA}]$$

when sinking.

where:

- i = 1 to total number of buffers
- V<sub>S</sub> = Total supply voltage of buffer
- V<sub>SA</sub> = Total supply voltage of V<sub>COM</sub>
- I<sub>SMAX</sub> = Maximum quiescent current per channel
- I<sub>SA</sub> = Maximum quiescent current of V<sub>COM</sub>
- V<sub>OUT</sub><sup>i</sup> = Maximum output voltage of the application
- V<sub>OUTA</sub> = Maximum output voltage of V<sub>COM</sub>
- I<sub>LOAD</sub><sup>i</sup> = Load current of buffer
- I<sub>LA</sub> = Load current of V<sub>COM</sub>

If we set the two P<sub>DMAX</sub> equations equal to each other, we can solve for the R<sub>LOAD</sub>'s to avoid device overheat. The package power dissipation curves provide a convenient way to see if the device will overheat. The maximum safe power dissipation can be found graphically, based on the package type and the ambient temperature. By using the previous equation, it is a simple matter to see if P<sub>DMAX</sub> exceeds the device's power derating curves.

### Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended, lead lengths should be as short as possible, and the power supply pins must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the V<sub>S-</sub> and V<sub>SA-</sub> pins are connected to ground, two 0.1µF ceramic capacitors should be placed from V<sub>S+</sub> and V<sub>SA+</sub> pins to ground. A 4.7µF tantalum capacitor should then be connected from V<sub>S+</sub> and V<sub>SA+</sub> pins to ground. One 4.7µF capacitor may be used for multiple devices. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used. Internally, V<sub>S+</sub> and V<sub>SA+</sub> are shorted together and V<sub>S-</sub> and V<sub>SA-</sub> are shorted together. To avoid high current density, the V<sub>S+</sub> pin and V<sub>SA+</sub> pin must be shorted in the PCB layout. Also, the V<sub>S-</sub> pin and V<sub>SA-</sub> pin must be shorted in the PCB layout.

**Important Note: The metal plane used for heat sinking of the device is electrically connected to the negative supply potential (V<sub>S-</sub> and V<sub>SA-</sub>). If V<sub>S-</sub> and V<sub>SA-</sub> are tied to ground, the thermal pad can be connected to ground. Otherwise, the thermal pad must be isolated from any other power planes.**
