

Features

- Package 8x10x1.4mm
- GSM900 P_{OUT} 33.3dBm
- DCS1800 P_{OUT} 32.0dBm
- Integrated Antenna Switch and Harmonic Filtering
- Dedicated RX Ports
- IEC 61000-4-2 Compliant, 8kV on Antenna Port
- Enhanced PowerStar™ Architecture to Facilitate TRP Performance
- Automatic V_{BATT} Tracking Circuit

Applications

- GSM900/DCS1800 Products
- GPRS Class 10 Compatible
- PowerStar™ Module
- 3V Dual-Band Handsets
- Portable Battery-Powered Equipment

Functional Block Diagram

Product Description

The RF3283 is a high-power, high-efficiency transmit module containing RFMD's PowerStar™ integrated power control, integrated pHEMT front end antenna switch and harmonic filtering functionality. All of which combine to provide for best in class harmonic emission control and RX and TX insertion loss. The device is self-contained with 50Ω input and output terminals with no matching components required. The integrated power control function based on RFMD's patented PowerStar™ control is incorporated, eliminating the need for directional couplers, detector diodes, power control ASIC's, and other power control circuitry; this allows the module to be driven directly from the DAC output. The device is designed for use as the final portion of the transmit chain in dual-band applications utilizing GSM900/DCS1800 and eliminates the need for PA to antenna switch module matching. On-board power control provides over 70dB control range. The integrated antenna switch allows true dual-band TX and RX functionality.

Absolute Maximum Ratings

Parameter	Rating	Unit
Supply Voltage	-0.3 to +6.0	V
Power Control Voltage (V_{RAMP})	-0.3 to +1.8	V
Input RF Power	+10	dBm
Max Duty Cycle	25	%
Output Load VSWR	20:1	
Operating Case Temperature	-30 to +85	°C
Storage Temperature	-55 to +150	°C

Caution! ESD sensitive device.

Exceeding any one or a combination of the Absolute Maximum Rating conditions may cause permanent damage to the device. Extended application of Absolute Maximum Rating conditions to the device may reduce device reliability. Specified typical performance or functional operation of the device under Absolute Maximum Rating conditions is not implied.

RoHS status based on EUDirective2002/95/EC (at time of this document revision).

Theory of Operation

Product Description

The RF3283 is a high-power, high-efficiency, transmit module (TXM) with fully-integrated power control functionality, harmonic filtering, band selectivity, and TX/RX switching. The TXM is self-contained, with 50Ω I/O terminals with two RX ports allowing true dual-band operation. The power control function eliminates all power control circuitry, including directional couplers, diode detectors, and power control ASIC's, etc. The power control capability provides 50dB continuous control range, and 70dB total control range, using a DAC-compatible, analog voltage input. Output power variations into varying load impedance are minimized by the power control circuitry in order to meet Total Radiated Power (TRP) requirements. The TX Enable feature provides for PA activation (TX mode) or RX mode/Stand-by. Internal switching provides a low-loss, low-distortion path from the Antenna port to the TX path (or RX port), while maintaining proper isolation. Integrated filtering provides ETSI compliant harmonic suppression at the antenna port even under high mismatch conditions, which is important as modern antennas today often present a load that significantly deviates from nominal impedance.

Overview

The RF3283 is a true dual-band GSM900/DCS1800 power amplifier module with fully integrated power control and antenna switch module eliminating the need for the complicated control loop design, harmonic filters, TX/RX switch and possible matching components. The power control loop can be driven directly from the DAC output in the baseband circuit. The module has two RX ports for GSM900/DCS1800 bands of operation. To control the mode of operation, there are four logic control signals: TX Enable, B1, B2, and B3. If control signals are limited, B3 may remain in the high state for all modes of operation.

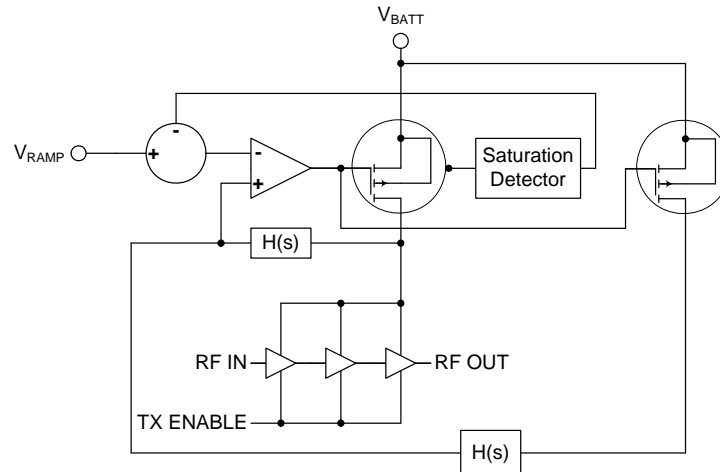

Module Control and Antenna Switch Logic

Mode	TX_EN	B1	B2	B3
Off	0	0	0	0
Low Band RX (GSM900)	0	0	0	1
High Band RX (DCS1800)	0	0	1	1
Low Band Pre-TX (PA On/Switch Off) (GSM900)	1	1	0	0
Low Band TX (PA On/Switch On) (GSM900)	1	1	0	1
High Band Pre-TX (PA On/Switch Off) (DCS1800)	1	1	1	0
High Band TX (PA On/Switch On) (DCS1800)	1	1	1	1

Table 1.

Power Control Theory of Operation

Most power control systems in GSM sense either forward power or collector/drain current. The RF3283 uses RFMD's Power-Star™ collector voltage control instead of a power detector. A high-speed control loop is incorporated to regulate the collector voltage of the amplifier while the stages are held at a constant bias. The V_{RAMP} signal is multiplied by a factor of approximately 2.65, and the collector voltage for all three stages is regulated to the multiplied V_{RAMP} voltage. This circuit is what performs the V_{BATT} tracking so no external V_{RAMP} adjustment is necessary. By doing so, the power amplifier can operate over a wider range of V_{RAMP} values, and can meet transient spectrum requirements at lower V_{CC} values. In addition, a current mirror is added to sense the power amplifier current. This loop senses the current, and feeds a voltage back into the control loop, and the collector voltage is further compensated to limit power and current variation. This allows for more efficient operation under mismatch conditions. Under nominal conditions, this loop is not activated, and is seemingly transparent. The basic circuit is shown in the following diagram.

By regulating the power, the stages are held in saturation across all power levels. As the required output power is decreased from full power down to -15dBm, the collector voltage is also decreased. This regulation of output power is demonstrated in Equation 1 where the relationship between collector voltage and output power is shown. Although load impedance affects output power, supply fluctuations are the dominate mode of power variations. With the RF3283 regulating, there are several key factors to consider in the implementation of a transmitter solution for a mobile phone. Some of them are:

$$P_{dBm} = 10 \cdot \log \left[\frac{(2 \cdot V_{CC} - V_{SAT})^2}{8 \cdot R_{LOAD} \cdot 10^{-3}} \right] \quad (\text{Eq. 1})$$

- Effective efficiency (η_{EFF})
- Current draw and system efficiency
- Power variation due to Supply Voltage
- Power variation due to frequency
- Power variation due to temperature
- Input impedance variation
- Noise power
- Loop stability
- Loop bandwidth variations across power levels
- Burst timing and transient spectrum trade offs
- Harmonics
- Post PA loss
- Insertion loss in receive ports
- TX power leakage into the RX ports
- Performance during VSWR
- Time needed to implement the solution
- Needed board area for the solution

Talk time and power management are key concerns in transmitter design since the power amplifier is the leading current consumer in a mobile terminal. Considering only the power amplifier's efficiency does not provide a true picture for the total system efficiency. It is important to consider effective efficiency which is represented by η_{EFF} . (η_{EFF} considers the loss between the PA and antenna and is a more accurate measurement to determine how much current will be drawn in the application). η_{EFF} is defined by the following relationship (Equation 2):

$$\eta_{EFF} = \frac{10^{\frac{P_{PA} + P_{LOSS}}{10}} - 10^{\frac{P_{IN}}{10}}}{V_{BAT} \cdot I_{BAT} \cdot 10} \quad (\text{Eq. 2})$$

Where P_{PA} is the output power from the PA, P_{LOSS} the insertion loss and P_{IN} the input power to the PA. The RF3283 improves the effective efficiency by minimizing the P_{LOSS} term in the equation. An ASM may have a typical loss of 1.2dB in LB and 1.4dB in high band. To be added to this is trace losses and mismatch losses. A post PA loss of 1.5dB in LB and 1.8dB in HB is common. With the integration of a low loss pHEMT switch and matching network in the same module, higher system efficiency can be achieved.

The components following the power amplifier often have insertion loss variation with respect to frequency. Usually, there is some length of microstrip that follows the power amplifier. There is also a frequency response found in directional couplers due to variation in the coupling factor over frequency, as well as the sensitivity of the detector diode. Since the RF3283 does not use a directional coupler with a diode detector, these variations do not occur. Also the TX/RX switch with low pass filters that usually follows the PA may contribute to frequency variation. The TX/RX switch incorporated in the RF3283 is very broadband and does not contribute to frequency roll off. Traditionally working with PA modules, some matching network is necessary between the PA output and the input of the TX/RX switch in order to get best possible performance. This work no longer has to be carried out, as this matching network is included in the RF3283.

Noise power in PA's where output power is controlled by changing the bias voltage is often a problem when backing off of output power. The reason is that the gain is changed in all stages and according to the noise formula (Equation 3),

$$F_{TOT} = F1 + \frac{F2 - 1}{G1} + \frac{F3 - 1}{G1 \cdot G2} \quad (\text{Eq. 3})$$

The noise figure depends on noise factor and gain in all stages. The bias point of the RF3283 is kept constant, therefore the gain in the first stage is always high and the overall noise power is not increased when decreasing output power.

Power control loop stability often presents many challenges to transmitter design. Designing a proper power control loop involves trade-offs affecting stability, transient spectrum and burst timing.

The RF3283 loop bandwidth is determined by internal bandwidth and does not change with respect to power levels. This makes it easier to maintain loop stability with a high bandwidth loop since the bias voltage and collector voltage do not vary. An often overlooked problem in PA control loops is that a delay not only decreases loop stability it also affects the burst timing when, for instance the input power from the VCO decreases (or increases) with respect to temperature or supply voltage. The burst timing then appears to shift to the right especially at low power levels. The RF3283 is insensitive to a change in input power and the burst timing is constant and requires no software compensation. Switching transients occur when the up and down ramp of the burst is not smooth enough or suddenly changes shape. If the control slope of a PA has an inflection point within the output power range or if the slope is simply too steep it is difficult to prevent switching transients. Controlling the output power by changing the collector voltage is as earlier described based on the physical relationship between voltage swing and output power. Furthermore, all stages are kept constantly biased so inflection points are nonexistent.

Harmonics are natural products of high efficiency power amplifier design. An ideal class “E” saturated power amplifier will produce a perfect square wave. Looking at the Fourier transform of a square wave reveals high harmonic content. Although this is common to all power amplifiers, there are other factors that contribute to conducted harmonic content as well. With most power control methods a peak power diode detector is used to rectify and sense forward power. Through the rectification process there is additional squaring of the waveform resulting in higher harmonics. The RF3283 address this by eliminating the need for the detector diode. In addition, the RF3283 provides integrated harmonic filtering. Therefore the harmonics coming out of the PA should represent the maximum power of the harmonics throughout the transmit chain. This is based upon proper harmonic termination of the transmit port.

Performance under VSWR

Often overlooked when designing transmitters is the fact that they normally operate under mismatch conditions while they are designed to operate only under perfect 50 ohm loads. This means that in the real application, performance is degraded. This performance degradation may include reduction in output power, increased harmonic levels, increased transient spectrum and catastrophic failures, breakdown. Traditionally designers have verified that the PA does not break during mismatch and this is all verification that has been carried out during mismatch. Modern antennas in handsets often present a load that significantly deviates from nominal impedance. A VSWR of 5:1 is not uncommon. In order not to disturb other phones in the same and close by cells, it is important that the ETSI specifications for transient spectrum, burst timing and spurious emission are fulfilled even during mismatch conditions. The RF3283 is designed to maintain its performance even under high antenna mismatch conditions.

The PowerStar™ methodology utilized in the RF3283 allows the transient spectrum in normal operation to be in the order of -35dBm to -40dBm but also both transient spectrum and the power versus time performance is unaffected even under mismatch conditions. Power output variation is minimized as well as the total current consumption. In addition, the harmonic level fluctuations are significantly decreased.

TX/RX Switch

The pHEMT switch integrated in the RF3283 allows for a low loss connection between the antenna port and the two RX ports. The insertion loss in the TX and RX paths is lower than the loss for a traditional pin-diode switch solution, which means lower current consumption in TX mode and better receiver sensitivity. The integrated switch also allows for less design complexity since there is no need for power amplifier to antenna switch matching.

Evaluation Board Layout Board Size 2.0" x 2.0" Board Thickness 0.062", Board Material FR-4

PCB Design Requirements

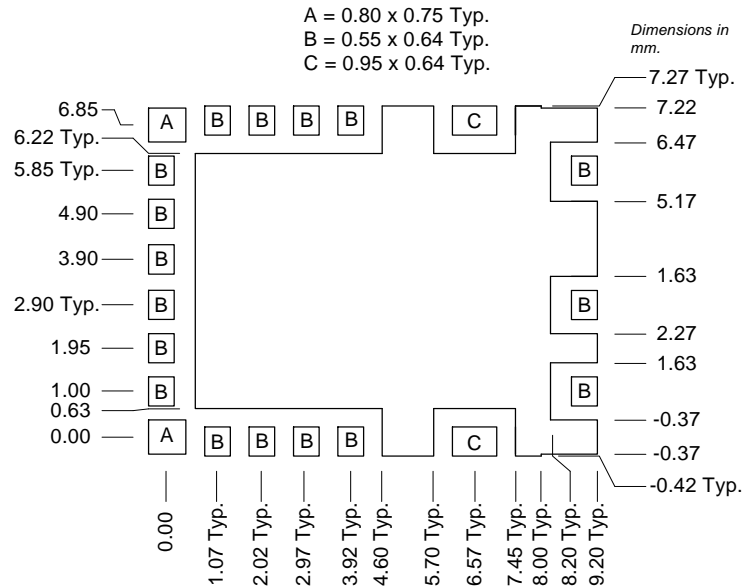

PCB Surface Finish

The PCB surface finish used for RFMD's qualification process is electroless nickel, immersion gold. Typical thickness is 3 inch to 8 inch gold over 180 inch nickel.

PCB Land Pattern Recommendation

PCB land patterns for RFMD components are based on IPC-7351 standards and RFMD empirical data. The pad pattern shown has been developed and tested for optimized assembly at RFMD. The PCB land pattern has been developed to accommodate lead and package tolerances. Since surface mount processes vary from company to company, careful process development is recommended.
