TDA9897; TDA9898

Multistandard hybrid IF processing

Rev. 04 — 25 May 2009 Product data sheet

1. General description

The Integrated Circuit (IC) is suitable for Intermediate Frequency (IF) processing including global multistandard Analog TV (ATV), Digital Video Broadcast (DVB) and mono FM radio using only 1 IC and 1 to 3 fixed Surface Acoustic Waves (SAWs) (application dependent). TDA9898 includes, TDA9897 excludes L and L-accent standard.

2. Features

2.1 General

- 5 V supply voltage
- I^2C-bus control over all functions
- Four I^2C-bus addresses provided; selection by programmable Module Address (MAD)
- Three I^2C-bus voltage level supported; selection via pin BVS
- Separate gain controlled amplifiers with input selector and conversion for incoming IF [analog Vision IF (VIF) or Sound IF (SIF) or Digital TV (DTV)] allows the use of different filter shapes and bandwidths
- All conventional ATV standards applicable by using DTV bandwidth window (SAW) filter
- Two 4 MHz reference frequency stages; the first one operates as crystal oscillator, the second one as external signal input
- Stabilizer circuit for ripple rejection and to achieve constant output signals
- Smallest size, simplest application
- ElectroStatic Discharge (ESD) protection for all pins

2.2 Analog TV processing

- Gain controlled wideband VIF amplifier; AC-coupled
- Multistandard true synchronous demodulation with active carrier regeneration: very linear demodulation, good intermodulation figures, reduced harmonics and excellent pulse response
- Integrated Nyquist processing, providing additionally image suppression for high adjacent channel selectivity
- Optional use of conventional Nyquist filter to support a wide range of applications
- Gated phase detector for L and L-accent standards
- Fully integrated VIF Voltage-Controlled Oscillator (VCO), alignment-free, frequencies switchable for all negative and positive modulated standards via I^2C-bus
- VIF Automatic Gain Control (AGC) detector for gain control; operating as a peak sync detector for negative modulated signals and as a peak white detector for positive modulated signals

- Optimized AGC modes for negative modulation; e.g. very fast reaction time for VIF and SIF
- Precise fully digital Automatic Frequency Control (AFC) detector with 4-bit Digital-to-Analog Converter (DAC); AFC bits can be read-out via I^2C-bus
- High precise Tuner AGC (TAGC) TakeOver Point (TOP) for negative modulated standards; TOP adjust via I^2C-bus
- TAGC TOP for positive standards and Received Signal Strength Indication (RSSI); adjustable via I^2C-bus or alternatively by potentiometer
- Fully integrated Sound Carrier (SC) trap for any ATV standard (SC at 4.5 MHz, 5.5 MHz, 6.0 MHz and 6.5 MHz)
- SIF AGC for gain controlled SIF amplifier and high-performance single-reference Quasi Split Sound (QSS) mixer
- Fully integrated sound BP filter supporting any ATV standard
- Optional use of external FM or AM sound BP filter
- AM sound demodulation for L and L-accent standard
- Alignment-free selective FM Phase-Locked Loop (PLL) demodulator with high linearity and low noise; external FM input
- Port function
- VIF AGC voltage monitor output or port function
- TAGC voltage monitor output or port function
- VIF AFC current or tuner, VIF, SIF or FM AGC voltage monitor output
- 2nd SIF output, gain controlled by internal SIF AGC or by internal FM carrier AGC for Digital Signal Processor (DSP)
- Fully integrated BP filter for 2nd SIF at 4.5 MHz, 5.5 MHz, 6.0 MHz or 6.5 MHz

2.3 Digital TV processing

- Applicable for terrestrial and cable TV reception
- 70 dB variable gain wideband IF amplifier (AC-coupled)
- Gain control via external control voltage (0 V to 3 V)
- 2 V (p-p) differential low IF (downconverted) output or 1 V (p-p) 1st IF output for direct Analog-to-Digital Converter (ADC) interfacing
- DVB downconversion with integrated selectivity for Low IF (LIF)
- Integrated anti-aliasing tracking low-pass filter
- Fully integrated synthesizer controlled oscillator with excellent phase noise performance
- Synthesizer frequencies for a wide range of world wide DVB standards (for IF center frequencies of e.g. 34.5 MHz, 36 MHz, 44 MHz and 57 MHz)
- TAGC detector for independent tuner gain control loop applications
- TAGC operating as peak detector, fast reaction time due to additional speed-up detector
- Port function
- TAGC voltage monitor output

2.4 FM radio mode

- Gain controlled wideband Radio IF (RIF) amplifier; AC-coupled
- Buffered RIF amplifier wideband output, gain controlled by internal RIF AGC
- Use of external FM sound BP filter
- 2nd RIF output, gain controlled by internal RIF AGC or by internal FM carrier AGC for DSP
- Alignment-free selective FM PLL demodulator with high linearity and low noise
- Precise fully digital AFC detector with 4-bit DAC; AFC bits read-out via I^2C-bus
- Port function
- Radio AFC or tuner, RIF or FM AGC voltage monitor output

3. Applications

- Analog and digital TV front-end applications for TV sets, recording applications and personal computer cards

[1] Values of video and sound parameters can be decreased at V_P = 4.5 V.

[2] AC load; C_L < 20 pF and R_L > 1 kΩ. The sound carrier frequencies (depending on TV standard) are attenuated by the integrated sound carrier traps.

[3] Condition: luminance range (5 steps) from 0 % to 100 %. Measurement value is based on 4 of 5 steps.

[4] The sound carrier trap can be bypassed by setting the I²C-bus bit W2[0] to logic 0; see Table 23. In this way the full composite video spectrum appears at pin CVBS. The video amplitude is reduced to 1.1 V (p-p).

[5] Measurement using 200 kHz high-pass filter, 5 MHz low-pass filter and subcarrier notch filter (*"ITU-T J.64"*).

[6] To match the AFC output signal to different tuning systems a current output is provided. The test circuit is given in Figure 19. The AFC steepness can be changed by resistors R1 and R2.

[7] With single-ended load for f_{IF} < 45 MHz $R_L \geq$ 1 kΩ and $C_L \leq$ 5 pF to ground and for f_{IF} = 45 MHz to 60 MHz R_L = 1 kΩ and $C_L \leq$ 3 pF to ground.

[8] This parameter is not tested during production and is only given as application information.

[9] Noise level is measured without input signal but AGC adjusted corresponding to the given input level.

[10] Set with AGC nominal output voltage as reference. For C/N measurement switch input signal off.

[11] The tolerance of the reference frequency determines the accuracy of VIF AFC, RIF AFC, FM demodulator center frequency, maximum FM deviation, sound trap frequency, LIF band-pass cut-off frequency, as well as the accuracy of the synthesizer.

[1] Recommendation: Leave this pin open or use a capacitor to GND, as shown in the application diagrams in Figure 47, Figure 48 and Figure 49.

8. Functional description

8.1 IF input switch

Different signal bandwidth can be handled by using two signal processing chains with individual gain control.

Switch configuration allows independent selection of filter for analog VIF and for analog SIF (used at same time) or DIF.

The switch takes into account correct signal selection for TAGC in the event of VIF and DIF signal processing.

8.2 VIF demodulator

ATV demodulation using 6 MHz DVB window (band-pass) filter (for 6 MHz, 7 MHz or 8 MHz channel width).

IF frequencies adapted to enable the use of different filter configurations. The Nyquist processing is integrated. The integrated Nyquist processing provides also adjacent channel suppression. Sideband switch supplies selection of lower or upper sideband (e.g. for L-accent).

For optional use of standard Nyquist filter the integrated Nyquist processing can be switched off.

Equalizer provides optimum pulse response at different standards [e.g. to cope with higher demands for Liquid Crystal Display (LCD) TV].

Integrated sound traps.

Sound trap reference independent from received 2nd sound IF (reference taken from integrated reference synthesizer).

IF level selection provides an optimum adaptation of the demodulator to high linearity or low noise.

8.3 VIF AGC and tuner AGC

8.3.1 Mode selection of VIF AGC

Peak white AGC for positive modulation mode with adaptation for speed up and black level AGC (using proven system from TDA9886).

For negative modulation mode equal response times for increasing or decreasing input level (optimum for amplitude fading) **or** normal peak AGC **or** ultra fast peak AGC.

8.3.2 VIF AGC monitor

VIF AGC DC voltage monitor output (with expanded internal characteristic).

VIF AGC read out via I^2C-bus (for IF level indication) with zero-calibration via TOP setting (TOP setting either via I^2C-bus or via TOP potentiometer).

8.3.3 Tuner AGC

Independent integral tuner gain control loop (not nested with VIF AGC). Integral characteristic provides high control accuracy.

Accurate setting of tuner control onset (TOP) for integral tuner gain control loop via I^2C-bus.

For L standard, TAGC remains VIF AGC nested, as from field experience in the past this narrowband TAGC gives best performance.

Thus two switchable TAGC systems for negative/DIF and positive modulation implemented.

L standard tuner time constant switching integrated (= speed up function in the event of step into high input levels), to speed up settling time.

For TOP setting at L standard, additional adjustment via optional potentiometer or I^2C-bus is provided.

Tuner AGC status bit provided.

8.4 DIF/SIF FM and AM sound AGC

External AGC control input for DIF. DIF includes direct IF and low IF.

Integrated gain control loop for SIF.

AGC control for FM SIF related to used SAW bandwidth.

Peak AGC control in the event of FM SIF.

Ultra fast SIF AGC time constant when VIF AGC set to ultra fast mode.

Slow average AGC control in the event of AM sound.

AM sound AGC related to AM sound carrier level.

Fast AM sound AGC in the event of fast VIF AGC (speed up).

SIF/FM AGC DC voltage monitor output with expanded internal characteristic.

8.5 Frequency phase-locked loop for VIF

Basic function as previous TDA9887 design.

PLL gating mode for positive and negative modulation, optional.

PLL optimized for either overmodulation or strong multipath.

8.6 DIF/SIF converter stage

Frequency conversion with sideband suppression.

Selection mode of upper or lower sideband for pass or suppression.

Suppression around zero for frequency conversion.

Conversion mode selection via synthesizer for DIF and radio mode or via VIF Frequency Phase-Locked Loop (FPLL) for TV QSS sound (FM/AM).

External BP filter (e.g. for 4.5 MHz) for additional filtering, optional.

Bypass mode selection for use of external filter.

Integrated SIF BP tracking filter for chroma suppression.

Integrated tracking filters for LIF.

Symmetrical output stages for direct IF, LIF and 2nd SIF (intercarrier signal).

Second narrowband gain control loop for 2nd SIF via FM PLL.

8.7 Mono sound demodulator

8.7.1 FM PLL narrowband demodulation

Additional external input for either TV or radio intercarrier signal.

FM carrier selection independent from VIF trap, because VIF trap uses reference via synthesizer.

FM wide and ultra wide mode with adapted loop bandwidth and different selectable FM acquisition window widths to cope with FM overmodulation conditions.

8.7.2 AM sound demodulation

AM sound envelope detector.

L and L-accent standard without SAW switching (done by sideband selection of SIF converter).

8.8 Audio amplifier

Different gain settings for FM sound to adapt to different FM deviation.

Switchable de-emphasis for FM sound.

Automatic mute function when FM PLL is unlocked.

Forced mute function.

Output amplifier for AM sound.

8.9 Synthesizer

The synthesizer supports SIF/DIF frequency conversion. A large set of synthesizer frequencies in steps of 0.5 MHz enables flexible combination of SAW filter and required conversion frequency.

Synthesizer loop internally adapted to divider ratio range for optimum phase noise requirement (loop bandwidth).

Synthesizer reference either via 4 MHz crystal or via an external source. Individual pins for crystal and external reference allows optimum interface definition and supports use of custom reference frequency offset.

8.10 I²C-bus transceiver and slave address

Four different I²C-bus device addresses to enable application with multi-IC use.

I²C-bus transceiver input ports can handle three different I²C-bus voltages.

Read-out functions as TDA9887 plus additional read out of VIF AGC and VIFLOCK, BLCKLEV and TAGC status.

6	VAGC	gain control voltage of VIF amplifier at pin MPP; see Table 31
5	SIFLEVEL	SIF level reduction
		1 = internal SIF level is reduced by 6 dB (only for AM sound)
		0 = internal SIF level is normal
4	VIDLEVEL	video level reduction
		1 = internal video level is reduced by 6 dB[1]
		0 = internal video level is normal
3	PORT1	output state; port 1 mode selection set to logic output port (W7[2] = 1)
		1 = output port is HIGH (external pull-up resistor needed)
		0 = output port is LOW
2	MODEP1	port 1 mode selection; pin PORT1
		1 = logic output port; level controlled by bit PORT1 (W7[3])
		0 = monitor output of VIF AGC voltage
1	FILOUTBP	external filter output signal source; see Figure 9
		1 = signal for external filter is obtained behind internal BP filter
		0 = signal for external filter is obtained behind SIF mixer
0	NYQOFF	internal Nyquist processing; see Table 24
		1 = internal Nyquist processing off[2]
		0 = internal Nyquist processing on

[1] Not recommended in combination with internal IF level set to reduced (W4[7] = 1).

[2] At internal Nyquist processing off (W7[0] = 1) it is mandatory to set the internal video level to normal (W7[4] = 0).

[1] Values of video and sound parameters can be decreased at V_P = 4.5 V.

[2] Condition for secure POR is a rise or fall time greater than 2 µs.

[3] This parameter is not tested during the production and is only given as application information for designing the receiver circuit.

[4] Level headroom for input level jumps during gain control setting.

[5] $B_{LF(-3dB)}$ = 100 kHz (damping factor d = 1.7; calculated with sync level within gain control range). Calculation of the VIF PLL filter by using the following formulae:

$$B_{LF(-3dB)} = K_O K_D R \text{, valid for } d \geq 1.2$$

$$d = \frac{1}{2} R \sqrt{2\pi K_O K_D C}$$

with the following parameters:

K_O = VCO steepness (Hz/V),

K_D = phase detector steepness (A/rad),

R = loop filter serial resistor (Ω),

C = loop filter serial capacitor (F),

$B_{LF(-3dB)}$ = −3 dB LF bandwidth (Hz),

d = damping factor.

[6] The VCO frequency offset related to the PC frequency is set to 1 MHz with white picture video modulation.

[7] AC load; C_L < 20 pF and R_L > 1 kΩ. The sound carrier frequencies (depending on TV standard) are attenuated by the integrated sound carrier traps.

[8] Condition: luminance range (5 steps) from 0 % to 100 %. Measurement value is based on 4 of 5 steps.

[9] Measurement using 200 kHz high-pass filter, 5 MHz low-pass filter and subcarrier notch filter (*"ITU-T J.64"*).

[10] Modulation VSB; sound carrier off; f_{video} > 0.5 MHz.

[11] Sound carrier on; f_{video} = 10 kHz to 10 MHz.

[12] The sound carrier trap can be bypassed by setting the I²C-bus bit W2[0] to logic 0; see Table 23. In this way the full composite video spectrum appears at pin CVBS. The video amplitude is reduced to 1.1 V (p-p).

[13] Measurement condition: with transformer, transmitter pre-correction on; reference is at 1 MHz.

[14] The response time is valid for a VIF input level range from 200 µV to 70 mV.

[15] AGC response time increased if no AGC event occurs during two lines at minimum.

[16] AGC response time increased if video level falls below half of selected level.

[17] Load applied to output pin causes signal loss. The resulting gain can be calculated by using $G_{v(load)} = G_v + 20log\left(\frac{R_L}{R_O + R_L}\right)$.

[18] See Figure 19 to smooth current pulses.

[19] To match the AFC output signal to different tuning systems a current output is provided. The test circuit is given in Figure 19. The AFC steepness can be changed by different applications of resistors R1 and R2.

[20] The AFC value of the VIF and RIF frequency is generated by using digital counting methods. The used counter resolution is provided with an uncertainty of ±1 bit corresponding to ±25 kHz. This uncertainty of ±25 kHz has to be added to the frequency accuracy parameter.

[21] Measured with an FM deviation of 25 kHz and the typical AF output voltage of 500 mV (RMS). The audio signal processing stage provides headroom of 6 dB with THD < 1.5 %. The I²C-bus bits W3[0] and W3[1] control the AF output signal amplitude from 0 dB to −18 dB in steps of −6 dB. Reducing the audio gain for handling a frequency deviation of more than 55 kHz avoids AF output signal clipping.

[22] Amplitude response depends on dimensioning of FM PLL loop filter.

[23] The lower AF cut-off frequency depends on the value of the capacitor at pin CAF. A value of C_{AF1} = 470 nF leads to $f_{-3dB(AF)l} \approx 20$ Hz and C_{AF1} = 220 nF leads to $f_{-3dB(AF)l} \approx 40$ Hz.

[24] For all signal-to-noise measurements the used VIF modulator has to meet the following specifications:

a) Incidental phase modulation for black-to-white jump less than 0.5 degrees.

b) QSS AF performance, measured with the television demodulator AMF2 (audio output, weighted signal-to-noise ratio) better than 60 dB (at deviation 27 kHz) for 6 kHz sine wave black-to-white video modulation.

c) Picture-to-sound carrier ratio PC / SC1 = 13 dB (transmitter).

[25] The PC / SC ratio is calculated as the addition of TV transmitter PC / SC1 ratio and SAW filter PC / SC1 ratio. This PC / SC ratio is necessary to achieve the weighted signal-to-noise values as noted. A different PC / SC ratio will change these values.

[26] Measurement condition is SC1 / SC2 ≥ 7 dB.

[27] The differential QSS signal output on pins OUT1A and OUT1B is analyzed by a test demodulator TDA9820. The signal-to-noise ratio of this device is better than 60 dB. The measurement is related to an FM deviation of ±27 kHz and in accordance with *"ITU-R BS.468-4"*.

[28] The tolerance of the reference frequency determines the accuracy of VIF AFC, RIF AFC, FM demodulator center frequency, maximum FM deviation, sound trap frequency, LIF band-pass cut-off frequency, as well as the accuracy of the synthesizer.

[29] The value of C_{pull} determines the accuracy of the resonance frequency of the crystal. It depends on the used type of crystal.

[30] The AC characteristics are in accordance with the I^2C-bus specification for fast mode (maximum clock frequency is 400 kHz). Information about the I^2C-bus can be found in the brochure *"The I^2C-bus and how to use it"* (order number 9398 393 40011).

[31] The SDA and SCL lines will not be pulled down if V_P is switched off.

[32] The threshold is dependent on V_P.

[33] The threshold is independent of V_P.

[1] Some parameters can be decreased at V_P = 4.5 V.

[2] This parameter is not tested during production and is only given as application information.

[3] Output current can be increased by application of single-ended resistor from each output pin to GND. Recommended resistor value is minimum 1 kΩ.

[4] With single-ended load for f_{IF} < 45 MHz $R_L \geq 1$ kΩ and $C_L \leq 5$ pF to ground and for f_{IF} = 45 MHz to 60 MHz R_L = 1 kΩ and $C_L \leq 3$ pF to ground.

[5] Noise level is measured without input signal but AGC adjusted corresponding to the given input level.

[6] Set with AGC nominal output voltage as reference. For C/N measurement switch input signal off.

[7] With single-ended load $R_L \geq 1$ kΩ and $C_L \leq 5$ pF to ground.

[8] The tolerance of the reference frequency determines the accuracy of VIF AFC, RIF AFC, FM demodulator center frequency, maximum FM deviation, sound trap frequency, LIF band-pass cut-off frequency, as well as the accuracy of the synthesizer.

[9] The value of C_{pull} determines the accuracy of the resonance frequency of the crystal. It depends on the used type of crystal.

[1] Calculation of the PLL loop filter by using the following formulae:

$$B_{LF(-3dB)} = \frac{K_O}{N} K_D R_{LFSYN2}$$, valid for d ≥ 1.2

$$d = \frac{1}{2} R_{LFSYN2} \sqrt{2\pi \frac{K_O}{N} K_D C_{LFSYN2}}$$

with the following parameters:

K_O = VCO steepness (Hz/V),

N = divider ratio: $N = \frac{f_{VCO}}{0.5\ MHz}$,

K_D = phase detector steepness (A/rad),

R_{LFSYN2} = synthesizer loop filter serial resistor (Ω),

C_{LFSYN2} = synthesizer loop filter serial capacitor (F),

$B_{LF(-3dB)}$ = –3 dB LF bandwidth (Hz),

d = damping factor.

[2] If more than one frequency range is used in the application, then the smallest resistor value should be applied.

16. Soldering of SMD packages

This text provides a very brief insight into a complex technology. A more in-depth account of soldering ICs can be found in Application Note *AN10365 "Surface mount reflow soldering description"*.

16.1 Introduction to soldering

Soldering is one of the most common methods through which packages are attached to Printed Circuit Boards (PCBs), to form electrical circuits. The soldered joint provides both the mechanical and the electrical connection. There is no single soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and Surface Mount Devices (SMDs) are mixed on one printed wiring board; however, it is not suitable for fine pitch SMDs. Reflow soldering is ideal for the small pitches and high densities that come with increased miniaturization.

16.2 Wave and reflow soldering

Wave soldering is a joining technology in which the joints are made by solder coming from a standing wave of liquid solder. The wave soldering process is suitable for the following:

- Through-hole components
- Leaded or leadless SMDs, which are glued to the surface of the printed circuit board

Not all SMDs can be wave soldered. Packages with solder balls, and some leadless packages which have solder lands underneath the body, cannot be wave soldered. Also, leaded SMDs with leads having a pitch smaller than ~0.6 mm cannot be wave soldered, due to an increased probability of bridging.

The reflow soldering process involves applying solder paste to a board, followed by component placement and exposure to a temperature profile. Leaded packages, packages with solder balls, and leadless packages are all reflow solderable.

Key characteristics in both wave and reflow soldering are:

- Board specifications, including the board finish, solder masks and vias
- Package footprints, including solder thieves and orientation
- The moisture sensitivity level of the packages
- Package placement
- Inspection and repair
- Lead-free soldering versus SnPb soldering

16.3 Wave soldering

Key characteristics in wave soldering are:

- Process issues, such as application of adhesive and flux, clinching of leads, board transport, the solder wave parameters, and the time during which components are exposed to the wave
- Solder bath specifications, including temperature and impurities

16.4 Reflow soldering

Key characteristics in reflow soldering are:

- Lead-free versus SnPb soldering; note that a lead-free reflow process usually leads to higher minimum peak temperatures (see Figure 54) than a SnPb process, thus reducing the process window
- Solder paste printing issues including smearing, release, and adjusting the process window for a mix of large and small components on one board
- Reflow temperature profile; this profile includes preheat, reflow (in which the board is heated to the peak temperature) and cooling down. It is imperative that the peak temperature is high enough for the solder to make reliable solder joints (a solder paste characteristic). In addition, the peak temperature must be low enough that the packages and/or boards are not damaged. The peak temperature of the package depends on package thickness and volume and is classified in accordance with Table 58 and 59

Table 58. SnPb eutectic process (from J-STD-020C)

Package thickness (mm)	Package reflow temperature (°C)	
	Volume (mm^3)	
	< 350	≥ 350
< 2.5	235	220
≥ 2.5	220	220

Table 59. Lead-free process (from J-STD-020C)

Package thickness (mm)	Package reflow temperature (°C)		
	Volume (mm^3)		
	< 350	350 to 2000	> 2000
< 1.6	260	260	260
1.6 to 2.5	260	250	245
> 2.5	250	245	245

Moisture sensitivity precautions, as indicated on the packing, must be respected at all times.

Studies have shown that small packages reach higher temperatures during reflow soldering, see Figure 54.

For further information on temperature profiles, refer to Application Note *AN10365 "Surface mount reflow soldering description"*.

17. Soldering of through-hole mount packages

17.1 Introduction to soldering through-hole mount packages

This text gives a very brief insight into wave, dip and manual soldering.

Wave soldering is the preferred method for mounting of through-hole mount IC packages on a printed-circuit board.

17.2 Soldering by dipping or by solder wave

Driven by legislation and environmental forces the worldwide use of lead-free solder pastes is increasing. Typical dwell time of the leads in the wave ranges from 3 seconds to 4 seconds at 250 °C or 265 °C, depending on solder material applied, SnPb or Pb-free respectively.

The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ($T_{stg(max)}$). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

17.3 Manual soldering

Apply the soldering iron (24 V or less) to the lead(s) of the package, either below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 °C and 400 °C, contact may be up to 5 seconds.

17.4 Package related soldering information

[1] For SDIP packages, the longitudinal axis must be parallel to the transport direction of the printed-circuit board.

[2] For PMFP packages hot bar soldering or manual soldering is suitable.
