Rev.9.0 00

The S-8520/8521 Series is a CMOS step-down switching regulator-controller with PWM control (S-8520 Series) and PWM / PFM switching control (S-8521 Series). The S-8520/8521 Series has a reference voltage source, an oscillation circuit, an error amplifier, and other components.

The S-8520 Series provides low-ripple power, high efficiency, and excellent transient characteristics due to a PWM control circuit capable of varying the duty ratio linearly from 0% up to 100%. The S-8520/8521 Series also has a soft-start circuit that prevents overshoot at startup.

The S-8521 Series works with either PWM control or PFM control. It normally operates using PWM control with a duty ratio of 25% to 100%, but under a light load, it automatically switches to PFM control with a duty ratio of 25%. The S-8520/8521 Series ensures high efficiency over a wide range of conditions for devices, from the standby mode to the operation.

By adding external Pch power MOS FET or PNP transistor, coil, capacitor, and externally connected diode, the S-8520/8521 Series can function as a step-down switching regulator, and is ideal for power supply units of portable devices due to small SOT-23-5 and the feature of low current consumption. It is also ideal for AC adapters due to the input voltage up to 16 V.

## ■ Features

• Low current consumption During operation:  $60 \mu A \text{ max}$ . (A, B types)

21  $\mu$ A max. (C, D types) 100  $\mu$ A max. (E, F types)

During shutdown: 0.5 µA max.

Input voltage: 2.5 V to 16 V (B, D, F types)

2.5 V to 10 V (A, C, E types)

Output voltage: Selectable between 1.5 V and 6.0 V in 0.1 V step

• Duty ratio: 0% to 100% PWM control (S-8520 Series)

25% to100% PWM / PFM switching control (S-8521 Series)

 External parts are Pch power MOS FET or PNP transistor, coil, diode, and capacitor only (When using PNP transistor, add base resistor and capacitor).

Oscillation frequency: 180 kHz typ. (A, B types)

60 kHz typ. (C, D types) 300 kHz typ. (E, F types)

• Soft-start function: 8 ms. typ. (A, B types)

12 ms. typ. (C, D types) 4.5 ms. typ. (E, F types)

• With a shutdown function

• With a built-in overload protection circuit Overload detection time: 4 ms. typ. (A type)

14 ms. typ. (C type)

1

2.6 ms. typ. (E type)

Lead-free, Sn 100%, halogen-free\*1

## STEP-DOWN, PWM CONTROL or PWM / PFM SWITCHABLE SWITCHING REGULATOR CONTROLLER S-8520/8521 Series Rev.9.0\_00

## **■** Applications

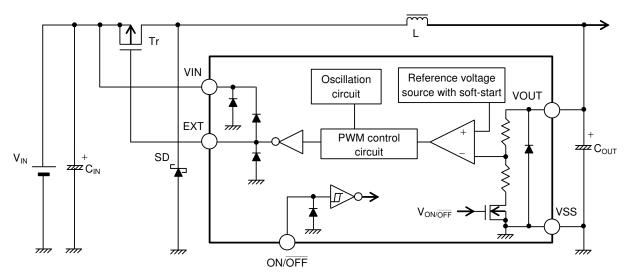

- On-board power supplies of battery devices for mobile phone, electronic notebooks, PDAs.
- Power supplies for audio equipment, including portable CD players and headphone stereo equipment.
- Fixed voltage power supply for cameras, video and communication devices.
- Power supplies for microcomputers
- $\bullet\,$  Conversion from NiH or four NiCd cells or two lithium-ion cells to 3.3 V / 3 V.
- Conversion of AC adapter input to 5 V / 3 V.

## ■ Package

• SOT-23-5

## Operation

#### 1. Switching control method

#### 1. 1 PWM control (S-8520 Series)

The S-8520 Series is a DC-DC converter using a pulse width modulation method (PWM) and features a low current consumption.

In conventional PFM DC-DC converters, pulses are skipped when the output load current is low, causing a fluctuation in the ripple frequency of the output voltage, resulting in an increase in the ripple voltage.

The switching frequency does not change, although the pulse width changes from 0 to 100% corresponding to each load current. The ripple voltage generated from switching can thus be removed easily through a filter because the switching frequency is constant. And the ripple voltage will be skipped to be low current consumption when the pulse width is 0% or it is no load, input current voltage is high.

#### 1. 2 PWM / PFM switching control (S-8521 Series)

S-8521 Series is a DC-DC converter that automatically switches between a pulse width modulation method (PWM) and a pulse frequency modulation method (PFM), depending on the load current, and features low current consumption.

The S-8521 Series operates under PWM control with the pulse width duty changing from 25 to 100% in a high output load current area.

The S-8521 Series operates under PFM control with the pulse width duty fixed at 25%, and pulses are skipped according to the load current. The oscillation circuit thus oscillates intermittently so that the resultant lower self current consumption prevents a reduction in the efficiency at a low load current. The switching point from PWM control to PFM control depends on the external devices (coil, diode, etc.), input voltage and output voltage. The S-8521 Series is an especially highly efficient DC-DC converter at an output current around  $100~\mu$ A.

#### 2. Soft start function

The S-8520/8521 Series has a built-in soft start-circuit. This circuit enables the output voltage ( $V_{OUT}$ ) to rise gradually over the specified soft start time (t), when power-on or when the  $ON/\overline{OFF}$  pin is at the "H" level. This prevents the output voltage from overshooting.

However, the soft-start function of this IC is not able to perfectly prevent a rush current from flowing to the load (Refer to **Figure 8**). Since this rush current depends on the input voltage and load conditions, Perform sufficient evaluation with actual device for design.

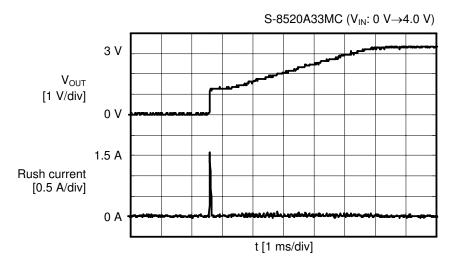

Figure 8 Waveforms of output voltage and rush current at soft start

#### 3. ON/OFF pin (Shutdown pin)

The ON/OFF pin stops or starts step-up operation.

Setting the  $ON/\overline{OFF}$  pin to the "L" level stops operation of all the internal circuits and reduces current consumption significantly. The EXT pin's voltage is set to the  $V_{IN}$  voltage level so that the switching transistor is turned off.

Do not use the ON/OFF pin in a floating state because it has the structure shown in **Figure 9** and is not pulled up or pulled down internally. Do not apply a voltage of between 0.3 V and 1.8 V to the ON/OFF pin because applying such a voltage increases the current consumption. When not using the ON/OFF pin, connect it to the VIN pin.

"H"	Operation	Set value
"L"	Stop	$V_{SS}$

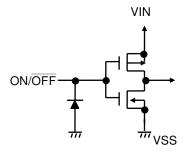

Figure 9

#### 4. Overload protection circuit (A, C, E types)

The A, C and E types of the S-8520/8521 Series have a built-in overload protection circuit.

If the output voltage drops under the overload status, the maximum duty status (100%) continues. If this 100% duty status lasts longer than the overload detection time ( $t_{pro}$ ), the circuit keeps the EXT pin at "H" to protect the switching transistor and inductor. When the overload protection circuit is functioning, the soft start works in the IC for the reference voltage, and the reference voltage rises slowly from 0 V. The reference voltage and the feedback voltage obtained by dividing the output voltage are compared to each other. While the reference voltage is low, the EXT pin keeps "H" and oscillation stops. If the reference voltage rises and exceeds the feedback voltage, oscillation restarts.

After oscillation is restarted, if a load is heavy and the EXT pin keeps the "L" level longer than the overload detection time ( $t_{pro}$ ), the circuit operates again, and the IC enters the intermittent operation mode by repeating the action described above. Once the overload state is off, the IC restarts the normal operation.

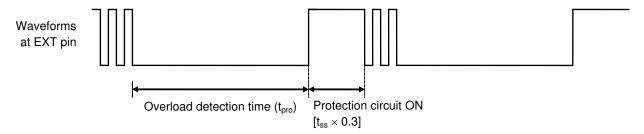

Figure 10 Waveforms at EXT pin when the overload protection circuit operates

#### 5. 100% duty cycle

The S-8520/8521 Series operates with a maximum duty cycle of 100%. When using the B, D and F types products, which do not have the overload protection circuit, the switching transistor keeps ON continually to supply current to the load, even in cases where the input voltage drops to the set value of output voltage or less. The output voltage in this case is; the voltage subtracting both of the inductance's DC resistance and the voltage drop by the switching resistor's ON-resistance, from the input voltage.

The A, C and E types that have the overload protection circuit cannot be used for continually supplying current to the load, as described above, because these types enter the intermittent operation mode by the overload protection circuit's operation, when 100% duty lasts longer than the overload detection time (t<sub>pro</sub>).

#### ■ Selection of Products and External Parts

## 1. Method for selecting series products

The S-8520/8521 Series is classified into 12 types, according to the control systems (PWM control and PWM / PFM switching control), the different oscillation frequencies, and set-up of an overload protection circuit. Please select the type for your application according to the following features.

#### 1. 1 Control systems

Two different control systems are available: PWM control system (S-8520 Series) and PWM / PFM switching control system (S-8521 Series).

For applications for which the load current greatly differs between standby and operation, if the efficiency during standby is important, applying the PWM/PFM switching system (S-8321 Series) realizes high efficiency during standby.

For applications for which switching noise is critical, applying the PWM control system (S-8320 Series) whereby switching frequency does not change due to load current allows the ripple voltage to be easily suppressed by using a filter.

#### 1. 2 Oscillation frequencies

Either oscillation frequency, 180 kHz (A and B types), 60 kHz (C and D types), or 300 kHz (E and F types), can be selected.

The A, B, E and F types have high oscillation frequency, how ripple voltage and excellent transient response characteristics. A small inductance can be used for these types because the peak current is low when inducing the same load current. Use of small output capacitors is effective for downsizing devices.

The C and D types, whereby lower oscillation frequency realizes smaller self-consumption current, are highly efficient under light loads. In particular, the D type, when combined with a PWM/PFM switching control system, drastically improves the operation efficiency when the output load current is approximately 100 mA.

#### 1.3 Overload protection circuit

Types are selectable the S-8520/8521 Series with the overload protection circuit (A, C and E types) or without the overload protection circuit (B, D and F types).

By the S-8520/8521 Series with the overload protection circuit (A, C and E types), the switching components and inductor can be protected because the overload protection circuit works and is set to the intermittent mode, in case of overload or load short-circuit.

But in case of supplying current to load by using 100% duty cycle, select the S-8520/8521 Series without the overload protection circuit (B, D and F types), according to the conditions of application.

The operation voltage differs in 10 V (A, B and E types) or 16 V (B, D and F types) whether the overload protection circuit is available or not.

Table 9 shows items for selecting the type according to the requirements of application. Select it matching the marks (O) for your requirement.

#### 2. Inductor

The inductance value (L value) has a strong influence on the maximum output current (I<sub>OUT</sub>) and efficiency (η).

The peak current ( $I_{PK}$ ) increases by decreasing L value and the stability of the circuit improves and  $I_{OUT}$  increases. If L value is decreased, the efficiency falls causing a decline in the current drive capacity for the switching transistor, and  $I_{OUT}$  decreases.

The loss of I<sub>PK</sub> by the switching transistor decreases by increasing L and the efficiency becomes the maximum at a certain L value. Further increasing L value decreases the efficiency due to the loss of the direct current resistance of the coil. I<sub>OUT</sub> also decreases.

For the S-8520/8521 Series, increasing the inductance value, the output voltage may be unstable in some cases, depending on the conditions of the input voltage, output voltage, and the load current. Perform sufficient evaluation under the actual condition and decide an optimum inductance value.

The recommended inductances are 47  $\mu H$  for A, B, C, D types and 22  $\mu H$  for E, F types.

Be careful of the allowable inductor current when choosing an inductor. Exceeding the allowable current of the inductor causes magnetic saturation, much lower efficiency and destruction of the IC chip due to a large current.

Choose an inductor so that  $I_{PK}$  does not exceed the allowable current.  $I_{PK}$  in continuous mode is calculated by the following equation:

$$I_{PK} = I_{OUT} + \frac{(V_{OUT} + V_F^{*2}) \times (V_{IN} - V_{OUT})}{2 \times f_{osc}^{*1} \times L \times (V_{IN} + V_F^{*2})}$$

\*1. f<sub>osc</sub>: Oscillation frequency

\*2. V<sub>F</sub>: Forward voltage of the diode

#### 3. Diode

Use an external diode that meets the following requirements :

- Its forward voltage is low (Schottky barrier diode is recommended).
- Its switching speed is high (50 ns max.).
- Its reverse direction voltage is higher than V<sub>IN</sub>.
- Its current rating is higher than IPK.

## 4. Capacitors (C<sub>IN</sub>, C<sub>OUT</sub>)

A capacitor for the input ( $C_{IN}$ ) improves efficiency by reducing power impedance and stabilizing the input current. Select the  $C_{IN}$  value according to impedance of the power supply to be used. Approximately 47 to 100  $\mu F$  is recommended for the capacitor depending on impedance of the power source and load current value.

For a capacitor for output  $(C_L)$ , select a large capacitance with low ESR (Equivalent Series Resistance) for smoothing the ripple voltage. However, capacitor with extremely small ESR such as ceramic capacitor (about 0.3  $\Omega$  or less) may destabilize the output voltage, according to the conditions of input and output voltages. A tantalum electrolyte capacitor is recommended. 47  $\mu$ F to 100  $\mu$ F is recommended for the capacitor.

#### 5. External transistor

Enhancement (Pch) MOS FET or bipolar (PNP) MOS FET can be used for external transistor.

#### 5. 1 Enhancement (Pch) MOS FET type

The EXT pin of the S-8520/8521 Series is capable of directly driving a Pch MOS FET with a gate capacity around 1000 pF.

When using a Pch MOS FET, 2 to 3% higher efficiency is provided because its switching speed is faster and it does not cause power dissipation, compared to PNP bipolar transistors.

The important parameters in selecting MOS FETs are the threshold voltage, the breakdown voltage between gate and source, the breakdown voltage between drain and source, the total gate capacity, the on-resistance, and the current ratings.

The EXT pin swings from voltages between  $V_{IN}$  to  $V_{SS}$ . If the input voltage is low, use a MOS FET with the low threshold voltage. If the input voltage is high, use a MOS FET having the breakdown voltage between gate and source higher several volts than the input voltage.

Immediately after the power-on or power-off (stopping the step-down operation), the input voltage will be applied between drain and source of the MOS FET. Use the breakdown voltage between drain and source also higher several volts than the input voltage.

The total gate capacity and the on-resistance affect efficiency.

Power dissipation when charging and discharging the gate capacity by switching operation affects efficiency, in the area of low load current, as the total gate capacity is larger and the input voltage is higher. Select a MOS FET with a small total gate capacity for efficiency at light load.

In the area of large load current, efficiency is affected by power dissipation caused by MOS FET's on-resistance. For efficiency at large load, select a MOS FET having as low on-resistance as possible.

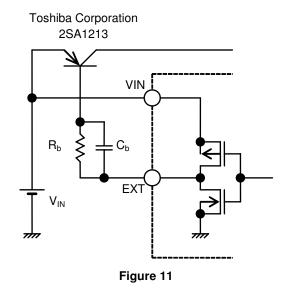

As for the current rating, select a MOS FET having the maximum continuous drain current rating higher than IPK.

For reference, this document has the data of efficiency. TM6201 by Toyota Industries Corporation for applications with an input voltage of 10 V or less, IRF7606 by International Rectifier Corporation Japan for applications with an input voltage over 10 V (Refer to "

Reference Data").

#### 5. 2 Bipolar PNP type

**Figure 11** shows the sample of circuit diagram using Toshiba Corporation 2SA1213 as the bipolar transistor (PNP). The  $h_{FE}$  value and the  $R_b$  value of that bipolar transistor determine the driving capacity, which is used for increasing the output current.

The R<sub>b</sub> value is given by the following equation:

$$R_b = \frac{V_{IN} - 0.7}{I_b} - \frac{0.4}{|I_{EXTL}|}$$

Calculate the necessary base current ( $I_b$ ) using the ( $h_{FE}$ ) value of bipolar transistor by the equation,  $I_b = \frac{I_{PK}}{h_{FE}}$ , and select a smaller  $R_b$  value.

A small  $R_b$  value increases the output current, but it also decreases efficiency. Determine the optimum value through experiment, since the base current may flow on the pulse, or voltage may drop due to wiring resistance. In addition, if speed-up capacitor  $C_b$  is connected in parallel with resistor  $R_b$ , as shown in **Figure 11**, the loss in switching will be reduced, leading to higher efficiency.

Determine the C<sub>b</sub> value using the following equation:

$$C_b \! \leq \! \frac{1}{2 \times \pi \times R_b \times f_{osc} \times 0.7}$$

Select the  $C_b$  value after performing sufficient evaluation since the optimum  $C_b$  value differs depending upon the characteristics of the bipolar transistor.

#### ■ Precautions

- Mount the external capacitors, the diode and the coil as close as possible to the IC, and secure grounding at a single location.
- Characteristics ripple voltage and spike noise occur in IC containing switching regulators. Moreover, rush current flows at the time of a power supply injection. Because these largely depend on the coil, the capacitor and impedance of power supply used, fully check them using an actually mounted model.
- The overload protection circuit of this IC performs the protective function by detecting the maximum duty time (100 %). In choosing the components, make sure that over currents generated by short-circuits in the load, etc., will not surpass the allowable dissipation of the switching transistor and inductor.
- Make sure that dissipation of the switching transistor (especially at a high temperature) does not exceed the allowable dissipation of the package.
- Do not apply an electrostatic discharge to this IC that exceeds the performance ratings of the built-in electrostatic protection circuit.
- SII claims no responsibility for any and all disputes arising out of or in connection with any infringement by products including this IC of patents owned by a third party.

## ■ Application Circuits

#### 1. External adjustment of output voltage

In the S-8550/8521 Series, by adding external resistors ( $R_A$ ,  $R_B$ ) and a capacitor ( $C_{FB}$ ), the output voltage can be adjusted or be set freely in the range of 1.5 to 6.0 V, as shown in **Figure 14**. Temperature gradient can be given by inserting a thermistor in series to  $R_A$  and  $R_B$ .

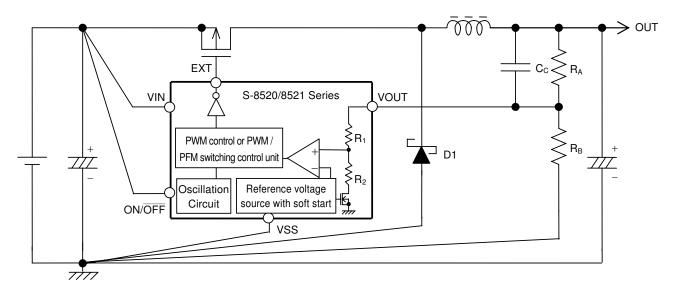

Figure 14

Caution The above connection diagram and constant will not guarantee successful operation. Perform through evaluation using the actual application to set the constant.

The S-8520/8521 Series have an internal impedance of  $R_1$  and  $R_2$  between the VOUT pin and the VSS pin, as shown in **Figure 14**.

Therefore, OUT (the output voltage) is determined by the output voltage value ( $V_{OUT}$ ) of the S-8520/8521 Series, and the ratio of the parallel resistance value of external resistance ( $R_B$ ) and internal resistances ( $R_1 + R_2$ ) of the IC, to external resistance ( $R_A$ ). The output voltage is expressed by the following equation:

OUT = 
$$V_{OUT} + V_{OUT} \times R_A \div (R_B //^{*1}(R_1 + R_2))$$

\*1. // shows the combined resistance in parallel.

The voltage accuracy of the OUT set by resistances ( $R_A$  and  $R_B$ ) is not only affected by the IC's output voltage accuracy ( $V_{OUT}$   $\pm 2.4$  %), but also by the absolute precision of external resistances ( $R_A$  and  $R_B$ ) in use and the absolute value deviations of internal resistances ( $R_1$  and  $R_2$ ) in the IC.

Let us designate the maximum deviations of the absolute value of  $R_A$  and  $R_B$  by  $R_A$  max. and  $R_B$  max., respectively, the minimum deviations by  $R_A$  min. and  $R_B$  min., respectively, and the maximum and minimum deviations of the absolute value of  $R_1$  and  $R_2$  in the IC by  $(R_1 + R_2)$  max. and  $(R_1 + R_2)$  min., respectively. Then, the minimum deviation value OUT min. and the maximum deviation value OUT max. of the OUT are expressed by the following equations:

OUT min. = 
$$V_{OUT} \times 0.976 + V_{OUT} \times 0.976 \times R_A$$
 min.  $\div$  ( $R_B$  max. // ( $R_1 + R_2$ ) max.)  
OUT max. =  $V_{OUT} \times 1.024 + V_{OUT} \times 1.024 \times R_A$  max.  $\div$  ( $R_B$  min. // ( $R_1 + R_2$ ) min.)

The voltage accuracy of the OUT cannot be made higher than the output voltage accuracy ( $V_{OUT}$  ±2.4%) of the IC itself, without adjusting the  $R_A$  and  $R_B$  involved. The closer the voltage value of the output OUT and the output voltage value ( $V_{OUT}$ ) of the IC are brought to one other, the more the output voltage remains immune to deviations in the absolute accuracy of  $R_A$  and  $R_B$  and the absolute value of  $R_1$  and  $R_2$  in the IC. In particular, to suppress the influence of deviations in  $R_1$  and  $R_2$  in the IC, a major contributor to deviations in the OUT, the  $R_A$  and  $R_B$  must be limited to a much smaller value than that of  $R_1$  and  $R_2$  in the IC.

On the other hand, a reactive current flows through  $R_A$  and  $R_B$ . This reactive current must be reduced to a negligible value with respect to the load current in the actual use of the IC so that the efficiency characteristics will not be degraded. This requires that the value of  $R_A$  and  $R_B$  be made sufficiently large.

However, too large a value (more than 1  $M\Omega$ ) for the  $R_A$  and  $R_B$  would make the IC vulnerable to external noise. Check the influence of this value on actual equipment.

There is a tradeoff between the voltage accuracy of the OUT and the reactive current. This should be taken into consideration based on the requirements of the intended application.

Deviations in the absolute value of the internal resistances ( $R_1$  and  $R_2$ ) in the IC vary with the output voltage of the S-8520/8521 Series, and are broadly classified as follows:

Output voltage	Deviations in the absolute value of R <sub>1</sub> and R <sub>2</sub> in the IC
1.5 V to 2.0 V	$5.16~\text{M}\Omega$ to $28.9~\text{M}\Omega$
2.1 V to 2.5 V	4.44 M $\Omega$ to 27.0 M $\Omega$
2.6 V to 3.3 V	3.60 M $\Omega$ to 23.3 M $\Omega$
3.4 V to 4.9 V	2.44 M $\Omega$ to 19.5 M $\Omega$
5.0 V to 6.0 V	2.45 M $\Omega$ to 15.6 M $\Omega$

Table 10

When a value of  $R_1 + R_2$  given by the equation indicated below is taken in calculating the voltage value of the output OUT, a median voltage deviation will be obtained for the OUT.

 $R_1 + R_2 = 2 \div (1 \div \text{maximum deviation in absolute value of } R_1 \text{ and } R_2 + 1 \div \text{minimum deviation in absolute value of } R_1 \text{ and } R_2)$ 

Moreover, add a capacitor  $(C_C)$  in parallel to the external resistance  $(R_A)$  in order to avoid output oscillations and other types of instability (Refer to **Figure 14**).

Make sure that  $C_{\text{\scriptsize C}}$  is larger than the value given by the following equation:

$$C_C[F] \ge 1 \div (2 \times \pi \times R_A[\Omega] \times 7.5 \text{ kHz})$$

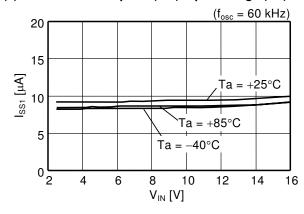

If a large  $C_{C}$  value is selected, a longer soft start time than the one set up in the IC will be set.

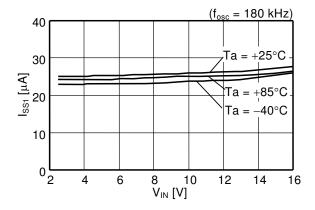

Caution The above connection diagram and constant will not guarantee successful operation. Perform through evaluation using the actual application to set the constant.
