

8086, 8086-1, 8086-2

16-Bit HMOS Microprocessor

The Intel 8086 high performance 16-bit CPU is available in three clock rates: 5, 8, 10 MHz. The CPU is implemented in N-Channel, depletion load, silicon gate technology (HMOS-III), and packaged in a 40-pin CERDIP or plastic package. The 8086 operates in both single processor and multiple processor configurations to achieve high performance levels.

Rochester Electronics Manufactured Components

Rochester branded components are manufactured using either die/wafers purchased from the original suppliers or Rochester wafers recreated from the original IP. All recreations are done with the approval of the OCM.

Parts are tested using original factory test programs or Rochester developed test solutions to guarantee product meets or exceeds the OCM data sheet.

Quality Overview

- ISO-9001
- AS9120 certification
- Qualified Manufacturers List (QML) MIL-PRF-38535
 - Class Q Military
 - Class V Space Level
- Qualified Suppliers List of Distributors (QSLD)
 - Rochester is a critical supplier to DLA and meets all industry and DLA standards.

Rochester Electronics, LLC is committed to supplying products that satisfy customer expectations for quality and are equal to those originally supplied by industry manufacturers.

The original manufacturer's datasheet accompanying this document reflects the performance and specifications of the Rochester manufactured version of this device. Rochester Electronics guarantees the performance of its semiconductor products to the original OEM specifications. 'Typical' values are for reference purposes only. Certain minimum or maximum ratings may be based on product characterization, design, simulation, or sample testing.

8086 16-BIT HMOS MICROPROCESSOR 8086/8086-2/8086-1

- Direct Addressing Capability 1 MByte of Memory
- Architecture Designed for Powerful Assembly Language and Efficient High Level Languages
- 14 Word, by 16-Bit Register Set with Symmetrical Operations
- 24 Operand Addressing Modes
- Bit, Byte, Word, and Block Operations
- 8 and 16-Bit Signed and Unsigned Arithmetic in Binary or Decimal Including Multiply and Divide
- Range of Clock Rates:
5 MHz for 8086,
8 MHz for 8086-2,
10 MHz for 8086-1
- MULTIBUS System Compatible Interface
- Available in EXPRESS
— Standard Temperature Range
— Extended Temperature Range
- Available in 40-Lead Cerdip and Plastic Package
(See Packaging Spec. Order #231389)

The Intel 8086 high performance 16-bit CPU is available in three clock rates: 5, 8 and 10 MHz. The CPU is implemented in N-Channel, depletion load, silicon gate technology (HMOS-III), and packaged in a 40-pin CERDIP or plastic package. The 8086 operates in both single processor and multiple processor configurations to achieve high performance levels.

Figure 2. 8086 Pin Configuration 231455-2

Table 1. Pin Description

The following pin function descriptions are for 8086 systems in either minimum or maximum mode. The "Local Bus" in these descriptions is the direct multiplexed bus interface connection to the 8086 (without regard to additional bus buffers).

| Symbol | Pin No. | Type | Name and Function | | | | | | | | | | | | | | | | | | |
|--|---------------------------------|---------------------------------|---|---------------------------------|---------------------------------|-----------------|---------|---|----------------|---|---|--------------------------------|----------|---|---------------------------------|---|---|------|---------------------------|--|--|
| AD ₁₅ -AD ₀ | 2-16, 39 | I/O | <p>ADDRESS DATA BUS: These lines constitute the time multiplexed memory/I/O address (T₁), and data (T₂, T₃, T_W, T₄) bus. A₀ is analogous to $\overline{\text{BHE}}$ for the lower byte of the data bus, pins D₇-D₀. It is LOW during T₁ when a byte is to be transferred on the lower portion of the bus in memory or I/O operations. Eight-bit oriented devices tied to the lower half would normally use A₀ to condition chip select functions. (See $\overline{\text{BHE}}$.) These lines are active HIGH and float to 3-state OFF during interrupt acknowledge and local bus "hold acknowledge".</p> | | | | | | | | | | | | | | | | | | |
| A ₁₉ /S ₆ , A ₁₈ /S ₅ , A ₁₇ /S ₄ , A ₁₆ /S ₃ | 35-38 | O | <p>ADDRESS/STATUS: During T₁ these are the four most significant address lines for memory operations. During I/O operations these lines are LOW. During memory and I/O operations, status information is available on these lines during T₂, T₃, T_W, T₄. The status of the interrupt enable FLAG bit (S₅) is updated at the beginning of each CLK cycle. A₁₇/S₄ and A₁₆/S₃ are encoded as shown. This information indicates which relocation register is presently being used for data accessing. These lines float to 3-state OFF during local bus "hold acknowledge."</p> <table border="1"> <thead> <tr> <th>A₁₇/S₄</th> <th>A₁₆/S₃</th> <th>Characteristics</th> </tr> </thead> <tbody> <tr> <td>0 (LOW)</td> <td>0</td> <td>Alternate Data</td> </tr> <tr> <td>0</td> <td>1</td> <td>Stack</td> </tr> <tr> <td>1 (HIGH)</td> <td>0</td> <td>Code or None</td> </tr> <tr> <td>1</td> <td>1</td> <td>Data</td> </tr> <tr> <td>S₆ is 0 (LOW)</td> <td></td> <td></td> </tr> </tbody> </table> | A ₁₇ /S ₄ | A ₁₆ /S ₃ | Characteristics | 0 (LOW) | 0 | Alternate Data | 0 | 1 | Stack | 1 (HIGH) | 0 | Code or None | 1 | 1 | Data | S ₆ is 0 (LOW) | | |
| A ₁₇ /S ₄ | A ₁₆ /S ₃ | Characteristics | | | | | | | | | | | | | | | | | | | |
| 0 (LOW) | 0 | Alternate Data | | | | | | | | | | | | | | | | | | | |
| 0 | 1 | Stack | | | | | | | | | | | | | | | | | | | |
| 1 (HIGH) | 0 | Code or None | | | | | | | | | | | | | | | | | | | |
| 1 | 1 | Data | | | | | | | | | | | | | | | | | | | |
| S ₆ is 0 (LOW) | | | | | | | | | | | | | | | | | | | | | |
| $\overline{\text{BHE}}$ /S ₇ | 34 | O | <p>BUS HIGH ENABLE/STATUS: During T₁ the bus high enable signal ($\overline{\text{BHE}}$) should be used to enable data onto the most significant half of the data bus, pins D₁₅-D₈. Eight-bit oriented devices tied to the upper half of the bus would normally use $\overline{\text{BHE}}$ to condition chip select functions. $\overline{\text{BHE}}$ is LOW during T₁ for read, write, and interrupt acknowledge cycles when a byte is to be transferred on the high portion of the bus. The S₇ status information is available during T₂, T₃, and T₄. The signal is active LOW, and floats to 3-state OFF in "hold". It is LOW during T₁ for the first interrupt acknowledge cycle.</p> <table border="1"> <thead> <tr> <th>$\overline{\text{BHE}}$</th> <th>A₀</th> <th>Characteristics</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Whole word</td> </tr> <tr> <td>0</td> <td>1</td> <td>Upper byte from/to odd address</td> </tr> <tr> <td>1</td> <td>0</td> <td>Lower byte from/to even address</td> </tr> <tr> <td>1</td> <td>1</td> <td>None</td> </tr> </tbody> </table> | $\overline{\text{BHE}}$ | A ₀ | Characteristics | 0 | 0 | Whole word | 0 | 1 | Upper byte from/to odd address | 1 | 0 | Lower byte from/to even address | 1 | 1 | None | | | |
| $\overline{\text{BHE}}$ | A ₀ | Characteristics | | | | | | | | | | | | | | | | | | | |
| 0 | 0 | Whole word | | | | | | | | | | | | | | | | | | | |
| 0 | 1 | Upper byte from/to odd address | | | | | | | | | | | | | | | | | | | |
| 1 | 0 | Lower byte from/to even address | | | | | | | | | | | | | | | | | | | |
| 1 | 1 | None | | | | | | | | | | | | | | | | | | | |
| RD | 32 | O | <p>READ: Read strobe indicates that the processor is performing a memory or I/O read cycle, depending on the state of the S₂ pin. This signal is used to read devices which reside on the 8086 local bus. RD is active LOW during T₂, T₃ and T_W of any read cycle, and is guaranteed to remain HIGH in T₂ until the 8086 local bus has floated. This signal floats to 3-state OFF in "hold acknowledge".</p> | | | | | | | | | | | | | | | | | | |

Table 1. Pin Description (Continued)

| Symbol | Pin No. | Type | Name and Function |
|----------------------------|---------|------|---|
| READY | 22 | I | READY: is the acknowledgement from the addressed memory or I/O device that it will complete the data transfer. The READY signal from memory/I/O is synchronized by the 8284A Clock Generator to form READY. This signal is active HIGH. The 8086 READY input is not synchronized. Correct operation is not guaranteed if the setup and hold times are not met. |
| INTR | 18 | I | INTERRUPT REQUEST: is a level triggered input which is sampled during the last clock cycle of each instruction to determine if the processor should enter into an interrupt acknowledge operation. A subroutine is vectored to via an interrupt vector lookup table located in system memory. It can be internally masked by software resetting the interrupt enable bit. INTR is internally synchronized. This signal is active HIGH. |
| $\overline{\text{TEST}}$ | 23 | I | $\overline{\text{TEST}}$: input is examined by the "Wait" instruction. If the $\overline{\text{TEST}}$ input is LOW execution continues, otherwise the processor waits in an "Idle" state. This input is synchronized internally during each clock cycle on the leading edge of CLK. |
| NMI | 17 | I | NON-MASKABLE INTERRUPT: an edge triggered input which causes a type 2 interrupt. A subroutine is vectored to via an interrupt vector lookup table located in system memory. NMI is not maskable internally by software. A transition from LOW to HIGH initiates the interrupt at the end of the current instruction. This input is internally synchronized. |
| RESET | 21 | I | RESET: causes the processor to immediately terminate its present activity. The signal must be active HIGH for at least four clock cycles. It restarts execution, as described in the Instruction Set description, when RESET returns LOW. RESET is internally synchronized. |
| CLK | 19 | I | CLOCK: provides the basic timing for the processor and bus controller. It is asymmetric with a 33% duty cycle to provide optimized internal timing. |
| V_{CC} | 40 | | V_{CC}: +5V power supply pin. |
| GND | 1, 20 | | GROUND |
| MN/ $\overline{\text{MX}}$ | 33 | I | MINIMUM/MAXIMUM: indicates what mode the processor is to operate in. The two modes are discussed in the following sections. |

3

The following pin function descriptions are for the 8086/8288 system in maximum mode (i.e., MN/ $\overline{\text{MX}}$ = V_{SS}). Only the pin functions which are unique to maximum mode are described; all other pin functions are as described above.

| | | | |
|--|-------|---|---|
| $\overline{S_2}, \overline{S_1}, \overline{S_0}$ | 26-28 | O | STATUS: active during T_4 , T_1 , and T_2 and is returned to the passive state (1, 1, 1) during T_3 or during T_W when READY is HIGH. This status is used by the 8288 Bus Controller to generate all memory and I/O access control signals. Any change by $\overline{S_2}$, $\overline{S_1}$, or $\overline{S_0}$ during T_4 is used to indicate the beginning of a bus cycle, and the return to the passive state in T_3 or T_W is used to indicate the end of a bus cycle. |
|--|-------|---|---|

| 1 | 0 | 1 | Read Memory | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 1 | 1 | 0 | Write Memory | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 1 | 1 | 1 | Passive | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| $\overline{RQ}/\overline{GT}_0$, $\overline{RQ}/\overline{GT}_1$ | 30, 31 | I/O | <p>REQUEST/GRANT: pins are used by other local bus masters to force the processor to release the local bus at the end of the processor's current bus cycle. Each pin is bidirectional with $\overline{RQ}/\overline{GT}_0$ having higher priority than $\overline{RQ}/\overline{GT}_1$. $\overline{RQ}/\overline{GT}$ pins have internal pull-up resistors and may be left unconnected. The request/grant sequence is as follows (see Page 2-24):</p> <ol style="list-style-type: none"> 1. A pulse of 1 CLK wide from another local bus master indicates a local bus request ("hold") to the 8086 (pulse 1). 2. During a T_4 or T_1 clock cycle, a pulse 1 CLK wide from the 8086 to the requesting master (pulse 2), indicates that the 8086 has allowed the local bus to float and that it will enter the "hold acknowledge" state at the next CLK. The CPU's bus interface unit is disconnected logically from the local bus during "hold acknowledge". 3. A pulse 1 CLK wide from the requesting master indicates to the 8086 (pulse 3) that the "hold" request is about to end and that the 8086 can reclaim the local bus at the next CLK. <p>Each master-master exchange of the local bus is a sequence of 3 pulses. There must be one dead CLK cycle after each bus exchange. Pulses are active LOW.</p> <p>If the request is made while the CPU is performing a memory cycle, it will release the local bus during T_4 of the cycle when all the following conditions are met:</p> <ol style="list-style-type: none"> 1. Request occurs on or before T_2. 2. Current cycle is not the low byte of a word (on an odd address). 3. Current cycle is not the first acknowledge of an interrupt acknowledge sequence. 4. A locked instruction is not currently executing. <p>If the local bus is idle when the request is made the two possible events will follow:</p> <ol style="list-style-type: none"> 1. Local bus will be released during the next clock. 2. A memory cycle will start within 3 clocks. Now the four rules for a currently active memory cycle apply with condition number 1 already satisfied. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| \overline{LOCK} | 29 | O | <p>\overline{LOCK}: output indicates that other system bus masters are not to gain control of the system bus while \overline{LOCK} is active LOW. The \overline{LOCK} signal is activated by the "LOCK" prefix instruction and remains active until the completion of the next instruction. This signal is active LOW, and floats to 3-state OFF in "hold acknowledge".</p> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Table 1. Pin Description (Continued)

| Symbol | Pin No. | Type | Name and Function | | |
|-----------------------------------|---------|----------------------------|---|-----------------|----------------------------------|
| QS ₁ , QS ₀ | 24, 25 | O | QUEUE STATUS: The queue status is valid during the CLK cycle after which the queue operation is performed. QS ₁ and QS ₀ provide status to allow external tracking of the internal 8086 instruction queue. | | |
| | | | QS ₁ | QS ₀ | Characteristics |
| | | | 0 (LOW) | 0 | No Operation |
| | | | 0 | 1 | First Byte of Op Code from Queue |
| 1 (HIGH) | 0 | Empty the Queue | | | |
| 1 | 1 | Subsequent Byte from Queue | | | |

The following pin function descriptions are for the 8086 in minimum mode (i.e., $MN/\overline{MX} = V_{CC}$). Only the pin functions which are unique to minimum mode are described; all other pin functions are as described above.

| | | | |
|--------------------|--------|-----|---|
| M/ \overline{IO} | 28 | O | STATUS LINE: logically equivalent to S ₂ in the maximum mode. It is used to distinguish a memory access from an I/O access. M/ \overline{IO} becomes valid in the T ₄ preceding a bus cycle and remains valid until the final T ₄ of the cycle (M = HIGH, IO = LOW). M/ \overline{IO} floats to 3-state OFF in local bus "hold acknowledge". |
| \overline{WR} | 29 | O | WRITE: indicates that the processor is performing a write memory or write I/O cycle, depending on the state of the M/ \overline{IO} signal. \overline{WR} is active for T ₂ , T ₃ and T _W of any write cycle. It is active LOW, and floats to 3-state OFF in local bus "hold acknowledge". |
| \overline{INTA} | 24 | O | \overline{INTA}: is used as a read strobe for interrupt acknowledge cycles. It is active LOW during T ₂ , T ₃ and T _W of each interrupt acknowledge cycle. |
| ALE | 25 | O | ADDRESS LATCH ENABLE: provided by the processor to latch the address into the 8282/8283 address latch. It is a HIGH pulse active during T ₁ of any bus cycle. Note that ALE is never floated. |
| DT/ \overline{R} | 27 | O | DATA TRANSMIT/RECEIVE: needed in minimum system that desires to use an 8286/8287 data bus transceiver. It is used to control the direction of data flow through the transceiver. Logically DT/ \overline{R} is equivalent to S ₁ in the maximum mode, and its timing is the same as for M/ \overline{IO} . (T = HIGH, R = LOW.) This signal floats to 3-state OFF in local bus "hold acknowledge". |
| \overline{DEN} | 26 | O | DATA ENABLE: provided as an output enable for the 8286/8287 in a minimum system which uses the transceiver. \overline{DEN} is active LOW during each memory and I/O access and for \overline{INTA} cycles. For a read or \overline{INTA} cycle it is active from the middle of T ₂ until the middle of T ₄ , while for a write cycle it is active from the beginning of T ₂ until the middle of T ₄ . \overline{DEN} floats to 3-state OFF in local bus "hold acknowledge". |
| HOLD, HLDA | 31, 30 | I/O | HOLD: indicates that another master is requesting a local bus "hold." To be acknowledged, HOLD must be active HIGH. The processor receiving the "hold" request will issue HLDA (HIGH) as an acknowledgement in the middle of a T ₄ or T ₁ clock cycle. Simultaneous with the issuance of HLDA the processor will float the local bus and control lines. After HOLD is detected as being LOW, the processor will LOWER the HLDA, and when the processor needs to run another cycle, it will again drive the local bus and control lines. Hold acknowledge (HLDA) and HOLD have internal pull-up resistors. The same rules as for $\overline{RQ}/\overline{GT}$ apply regarding when the local bus will be released. HOLD is not an asynchronous input. External synchronization should be provided if the system cannot otherwise guarantee the setup time. |

FUNCTIONAL DESCRIPTION

General Operation

The internal functions of the 8086 processor are partitioned logically into two processing units. The first is the Bus Interface Unit (BIU) and the second is the Execution Unit (EU) as shown in the block diagram of Figure 1.

These units can interact directly but for the most part perform as separate asynchronous operational processors. The bus interface unit provides the functions related to instruction fetching and queuing, operand fetch and store, and address relocation. This unit also provides the basic bus control. The overlap of instruction pre-fetching provided by this unit serves to increase processor performance through improved bus bandwidth utilization. Up to 6 bytes of the instruction stream can be queued while waiting for decoding and execution.

The instruction stream queuing mechanism allows the BIU to keep the memory utilized very efficiently. Whenever there is space for at least 2 bytes in the queue, the BIU will attempt a word fetch memory cycle. This greatly reduces "dead time" on the memory bus. The queue acts as a First-In-First-Out (FIFO) buffer, from which the EU extracts instruction bytes as required. If the queue is empty (following a branch instruction, for example), the first byte into the queue immediately becomes available to the EU.

The execution unit receives pre-fetched instructions from the BIU queue and provides un-relocated operand addresses to the BIU. Memory operands are passed through the BIU for processing by the EU, which passes results to the BIU for storage. See the Instruction Set description for further register set and architectural descriptions.

MEMORY ORGANIZATION

The processor provides a 20-bit address to memory which locates the byte being referenced. The memory is organized as a linear array of up to 1 million

bytes, addressed as 00000(H) to FFFFF(H). The memory is logically divided into code, data, extra data, and stack segments of up to 64K bytes each, with each segment falling on 16-byte boundaries. (See Figure 3a.)

All memory references are made relative to base addresses contained in high speed segment registers. The segment types were chosen based on the addressing needs of programs. The segment register to be selected is automatically chosen according to the rules of the following table. All information in one segment type share the same logical attributes (e.g. code or data). By structuring memory into relocatable areas of similar characteristics and by automatically selecting segment registers, programs are shorter, faster, and more structured.

Word (16-bit) operands can be located on even or odd address boundaries and are thus not constrained to even boundaries as is the case in many 16-bit computers. For address and data operands, the least significant byte of the word is stored in the lower valued address location and the most significant byte in the next higher address location. The BIU automatically performs the proper number of memory accesses, one if the word operand is on an even byte boundary and two if it is on an odd byte boundary. Except for the performance penalty, this double access is transparent to the software. This performance penalty does not occur for instruction fetches, only word operands.

Physically, the memory is organized as a high bank (D₁₅-D₈) and a low bank (D₇-D₀) of 512K 8-bit bytes addressed in parallel by the processor's address lines A₁₉-A₁. Byte data with even addresses is transferred on the D₇-D₀ bus lines while odd addressed byte data (A₀ HIGH) is transferred on the D₁₅-D₈ bus lines. The processor provides two enable signals, $\overline{\text{BHE}}$ and A₀, to selectively allow reading from or writing into either an odd byte location, even byte location, or both. The instruction stream is fetched from memory as words and is addressed internally by the processor to the byte level as necessary.

| Memory Reference Need | Segment Register Used | Segment Selection Rule |
|------------------------|-----------------------|---|
| Instructions | CODE (CS) | Automatic with all instruction prefetch. |
| Stack | STACK (SS) | All stack pushes and pops. Memory references relative to BP base register except data references. |
| Local Data | DATA (DS) | Data references when: relative to stack, destination of string operation, or explicitly overridden. |
| External (Global) Data | EXTRA (ES) | Destination of string operations: explicitly selected using a segment override. |

Figure 3a. Memory Organization

In referencing word data the BIU requires one or two memory cycles depending on whether or not the starting byte of the word is on an even or odd address, respectively. Consequently, in referencing word operands performance can be optimized by locating data on even address boundaries. This is an especially useful technique for using the stack, since odd address references to the stack may adversely affect the context switching time for interrupt processing or task multiplexing.

Figure 3b. Reserved Memory Locations

Certain locations in memory are reserved for specific CPU operations (see Figure 3b). Locations from

address FFFF0H through FFFFFH are reserved for operations including a jump to the initial program loading routine. Following RESET, the CPU will always begin execution at location FFFF0H where the jump must be. Locations 00000H through 003FFH are reserved for interrupt operations. Each of the 256 possible interrupt types has its service routine pointed to by a 4-byte pointer consisting of a 16-bit segment address and a 16-bit offset address. The pointer elements are assumed to have been stored at the respective places in reserved memory prior to occurrence of interrupts.

MINIMUM AND MAXIMUM MODES

The requirements for supporting minimum and maximum 8086 systems are sufficiently different that they cannot be done efficiently with 40 uniquely defined pins. Consequently, the 8086 is equipped with a strap pin (MN/MX) which defines the system configuration. The definition of a certain subset of the pins changes dependent on the condition of the strap pin. When MN/MX pin is strapped to GND, the 8086 treats pins 24 through 31 in maximum mode. An 8288 bus controller interprets status information coded into $\overline{S}_0, \overline{S}_2, \overline{S}_2$ to generate bus timing and control signals compatible with the MULTIBUS architecture. When the MN/MX pin is strapped to V_{CC} , the 8086 generates bus control signals itself on pins 24 through 31, as shown in parentheses in Figure 2. Examples of minimum mode and maximum mode systems are shown in Figure 4.

3

BUS OPERATION

The 8086 has a combined address and data bus commonly referred to as a time multiplexed bus. This technique provides the most efficient use of pins on the processor while permitting the use of a standard 40-lead package. This "local bus" can be buffered directly and used throughout the system with address latching provided on memory and I/O modules. In addition, the bus can also be demultiplexed at the processor with a single set of address latches if a standard non-multiplexed bus is desired for the system.

Each processor bus cycle consists of at least four CLK cycles. These are referred to as T_1, T_2, T_3 and T_4 (see Figure 5). The address is emitted from the processor during T_1 and data transfer occurs on the bus during T_3 and T_4 . T_2 is used primarily for changing the direction of the bus during read operations. In the event that a "NOT READY" indication is given by the addressed device, "Wait" states (T_W) are inserted between T_3 and T_4 . Each inserted "Wait" state is of the same duration as a CLK cycle. Periods

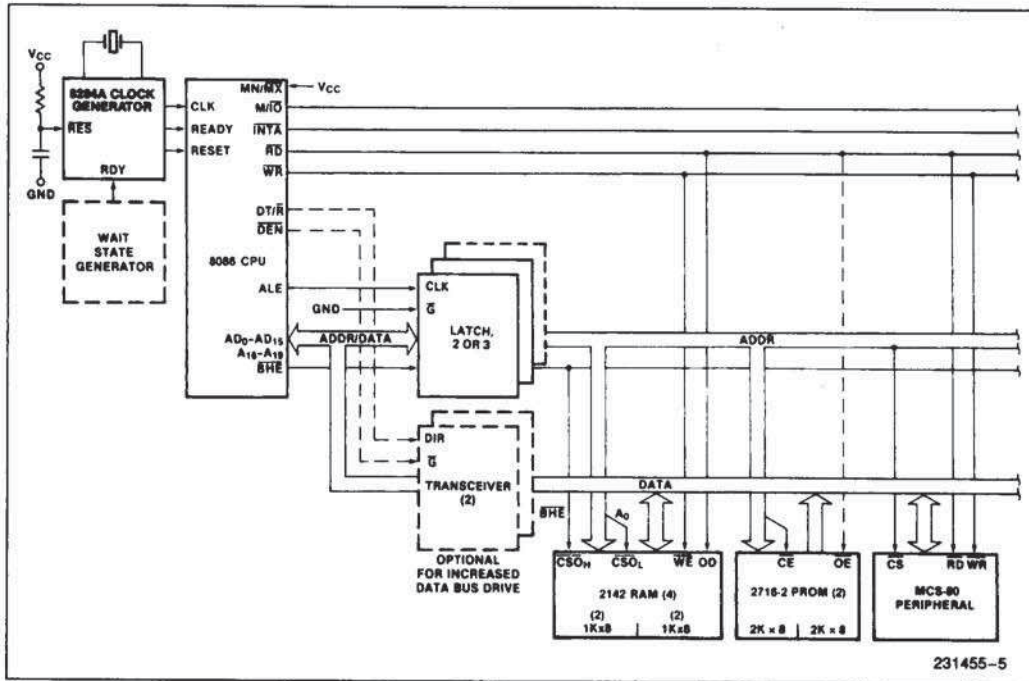

Figure 4a. Minimum Mode 8086 Typical Configuration

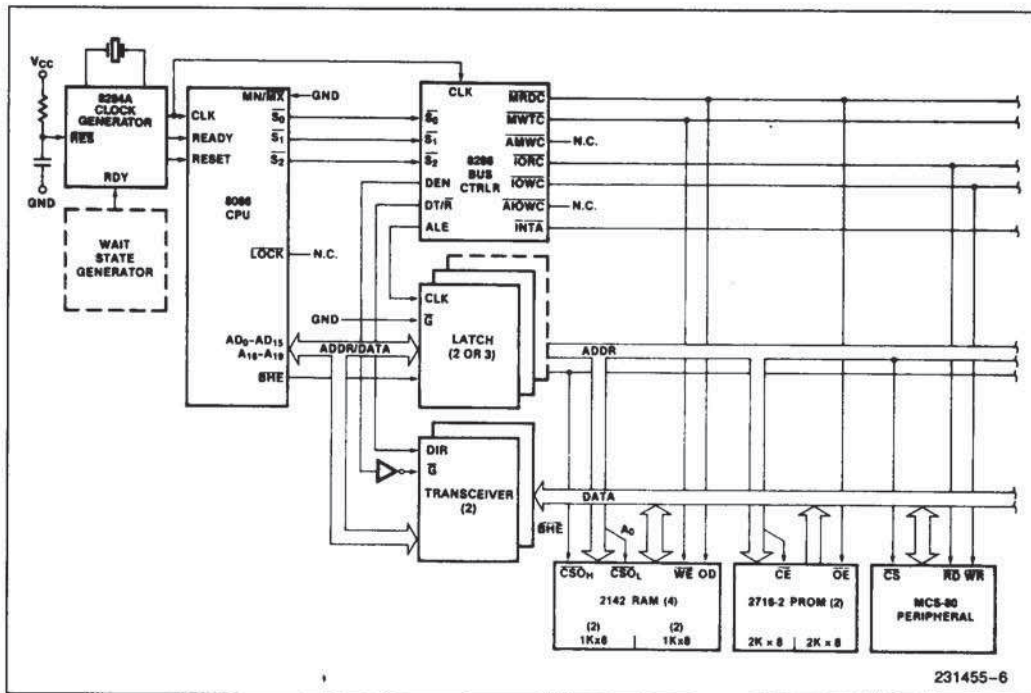

Figure 4b. Maximum Mode 8086 Typical Configuration

Status bits S_3 through S_7 are multiplexed with high-order address bits and the \overline{BHE} signal, and are therefore valid during T_2 through T_4 . S_3 and S_4 indicate which segment register (see Instruction Set description) was used for this bus cycle in forming the address, according to the following table:

| S_4 | S_3 | Characteristics |
|----------|-------|--------------------------------|
| 0 (LOW) | 0 | Alternate Data (extra segment) |
| 0 | 1 | Stack |
| 1 (HIGH) | 0 | Code or None |
| 1 | 1 | Data |

S_5 is a reflection of the PSW interrupt enable bit. $S_6 = 0$ and S_7 is a spare status bit.

I/O ADDRESSING

In the 8086, I/O operations can address up to a maximum of 64K I/O byte registers or 32K I/O word registers. The I/O address appears in the same format as the memory address on bus lines A_{15} – A_0 . The address lines A_{19} – A_{16} are zero in I/O operations. The variable I/O instructions which use register DX as a pointer have full address capability while the direct I/O instructions directly address one or two of the 256 I/O byte locations in page 0 of the I/O address space.

I/O ports are addressed in the same manner as memory locations. Even addressed bytes are transferred on the D_7 – D_0 bus lines and odd addressed bytes on D_{15} – D_8 . Care must be taken to assure that each register within an 8-bit peripheral located on the lower portion of the bus be addressed as even.

External Interface

PROCESSOR RESET AND INITIALIZATION

Processor initialization or start up is accomplished with activation (HIGH) of the RESET pin. The 8086 RESET is required to be HIGH for greater than 4 CLK cycles. The 8086 will terminate operations on the high-going edge of RESET and will remain dormant as long as RESET is HIGH. The low-going transition of RESET triggers an internal reset sequence for approximately 10 CLK cycles. After this interval the 8086 operates normally beginning with the instruction in absolute location FFFF0H (see Figure 3b). The details of this operation are specified in the Instruction Set description of the MCS-86 Family User's Manual. The RESET input is internally synchronized to the processor clock. At initialization the HIGH-to-LOW transition of RESET must occur no sooner than 50 μ s after power-up, to allow complete initialization of the 8086.

NMI asserted prior to the 2nd clock after the end of RESET will not be honored. If NMI is asserted after that point and during the internal reset sequence, the processor may execute one instruction before responding to the interrupt. A hold request active immediately after RESET will be honored before the first instruction fetch.

All 3-state outputs float to 3-state OFF during RESET. Status is active in the idle state for the first clock after RESET becomes active and then floats to 3-state OFF. ALE and HLDA are driven low.

INTERRUPT OPERATIONS

Interrupt operations fall into two classes; software or hardware initiated. The software initiated interrupts and software aspects of hardware interrupts are specified in the Instruction Set description. Hardware interrupts can be classified as non-maskable or maskable.

Interrupts result in a transfer of control to a new program location. A 256-element table containing address pointers to the interrupt service program locations resides in absolute locations 0 through 3FFH (see Figure 3b), which are reserved for this purpose. Each element in the table is 4 bytes in size and corresponds to an interrupt "type". An interrupting device supplies an 8-bit type number, during the interrupt acknowledge sequence, which is used to "vector" through the appropriate element to the new interrupt service program location.

NON-MASKABLE INTERRUPT (NMI)

The processor provides a single non-maskable interrupt pin (NMI) which has higher priority than the maskable interrupt request pin (INTR). A typical use would be to activate a power failure routine. The NMI is edge-triggered on a LOW-to-HIGH transition. The activation of this pin causes a type 2 interrupt. (See Instruction Set description.)

NMI is required to have a duration in the HIGH state of greater than two CLK cycles, but is not required to be synchronized to the clock. Any high-going transition of NMI is latched on-chip and will be serviced at the end of the current instruction or between whole moves of a block-type instruction. Worst case response to NMI would be for multiply, divide, and variable shift instructions. There is no specification on the occurrence of the low-going edge; it may occur before, during, or after the servicing of NMI. Another high-going edge triggers another response if it occurs after the start of the NMI procedure. The signal must be free of logical spikes in general and be free of bounces on the low-going edge to avoid triggering extraneous responses.

MASKABLE INTERRUPT (INTR)

The 8086 provides a single interrupt request input (INTR) which can be masked internally by software with the resetting of the interrupt enable FLAG status bit. The interrupt request signal is level triggered. It is internally synchronized during each clock cycle on the high-going edge of CLK. To be responded to, INTR must be present (HIGH) during the clock period preceding the end of the current instruction or the end of a whole move for a block-type instruction. During the interrupt response sequence further interrupts are disabled. The enable bit is reset as part of the response to any interrupt (INTR, NMI, software interrupt or single-step), although the FLAGS register which is automatically pushed onto the stack reflects the state of the processor prior to the interrupt. Until the old FLAGS register is restored the enable bit will be zero unless specifically set by an instruction.

During the response sequence (Figure 6) the processor executes two successive (back-to-back) interrupt acknowledge cycles. The 8086 emits the LOCK signal from T₂ of the first bus cycle until T₂ of the second. A local bus "hold" request will not be honored until the end of the second bus cycle. In the second bus cycle a byte is fetched from the external interrupt system (e.g., 8259A PIC) which identifies the source (type) of the interrupt. This byte is multiplied by four and used as a pointer into the interrupt vector lookup table. An INTR signal left HIGH will be continually responded to within the limitations of the enable bit and sample period. The INTERRUPT RETURN instruction includes a FLAGS pop which returns the status of the original interrupt enable bit when it restores the FLAGS.

HALT

When a software "HALT" instruction is executed the processor indicates that it is entering the "HALT" state in one of two ways depending upon which mode is strapped. In minimum mode, the processor issues one ALE with no qualifying bus control signals. In maximum mode, the processor issues appropriate HALT status on \overline{S}_2 , \overline{S}_1 , and \overline{S}_0 ; and the 8288 bus controller issues one ALE. The 8086 will not leave the "HALT" state when a local bus "hold" is entered while in "HALT". In this case, the processor reissues the HALT indicator. An interrupt request or RESET will force the 8086 out of the "HALT" state.

READ/MODIFY/WRITE (SEMAPHORE) OPERATIONS VIA LOCK

The LOCK status information is provided by the processor when directly consecutive bus cycles are required during the execution of an instruction. This provides the processor with the capability of performing read/modify/write operations on memory (via the Exchange Register With Memory instruction, for example) without the possibility of another system bus master receiving intervening memory cycles. This is useful in multi-processor system configurations to accomplish "test and set lock" operations. The LOCK signal is activated (forced LOW) in the clock cycle following the one in which the software "LOCK" prefix instruction is decoded by the EU. It is deactivated at the end of the last bus cycle of the instruction following the "LOCK" prefix instruction. While LOCK is active a request on a RQ/GT pin will be recorded and then honored at the end of the LOCK.

3

Figure 6. Interrupt Acknowledge Sequence

EXTERNAL SYNCHRONIZATION VIA TEST

As an alternative to the interrupts and general I/O capabilities, the 8086 provides a single software-testable input known as the $\overline{\text{TEST}}$ signal. At any time the program may execute a WAIT instruction. If at that time the $\overline{\text{TEST}}$ signal is inactive (HIGH), program execution becomes suspended while the processor waits for $\overline{\text{TEST}}$ to become active. It must remain active for at least 5 CLK cycles. The WAIT instruction is re-executed repeatedly until that time. This activity does not consume bus cycles. The processor remains in an idle state while waiting. All 8086 drivers go to 3-state OFF if bus "Hold" is entered. If interrupts are enabled, they may occur while the processor is waiting. When this occurs the processor fetches the WAIT instruction one extra time, processes the interrupt, and then re-fetches and re-executes the WAIT instruction upon returning from the interrupt.

Basic System Timing

Typical system configurations for the processor operating in minimum mode and in maximum mode are shown in Figures 4a and 4b, respectively. In minimum mode, the $\text{MN}/\overline{\text{MX}}$ pin is strapped to V_{CC} and the processor emits bus control signals in a manner similar to the 8085. In maximum mode, the $\text{MN}/\overline{\text{MX}}$ pin is strapped to V_{SS} and the processor emits coded status information which the 8288 bus controller uses to generate MULTIBUS compatible bus control signals. Figure 5 illustrates the signal timing relationships.

Figure 7. 8086 Register Model

SYSTEM TIMING—MINIMUM SYSTEM

The read cycle begins in T_1 with the assertion of the Address Latch Enable (ALE) signal. The trailing (low-going) edge of this signal is used to latch the address information, which is valid on the local bus at this time, into the address latch. The $\overline{\text{BHE}}$ and A_0 signals address the low, high, or both bytes. From T_1 to T_4 the $\text{M}/\overline{\text{IO}}$ signal indicates a memory or I/O operation. At T_2 the address is removed from the local bus and the bus goes to a high impedance state. The read control signal is also asserted at T_2 . The read ($\overline{\text{RD}}$) signal causes the addressed device to enable its data bus drivers to the local bus. Some time later valid data will be available on the bus and the addressed device will drive the READY line HIGH. When the processor returns the read signal to a HIGH level, the addressed device will again 3-state its bus drivers. If a transceiver is required to buffer the 8086 local bus, signals $\text{DT}/\overline{\text{R}}$ and $\overline{\text{DEN}}$ are provided by the 8086.

A write cycle also begins with the assertion of ALE and the emission of the address. The $\text{M}/\overline{\text{IO}}$ signal is again asserted to indicate a memory or I/O write operation. In the T_2 immediately following the address emission the processor emits the data to be written into the addressed location. This data remains valid until the middle of T_4 . During T_2 , T_3 , and T_4 the processor asserts the write control signal. The write ($\overline{\text{WR}}$) signal becomes active at the beginning of T_2 as opposed to the read which is delayed somewhat into T_2 to provide time for the bus to float.

The $\overline{\text{BHE}}$ and A_0 signals are used to select the proper byte(s) of the memory/I/O word to be read or written according to the following table:

| $\overline{\text{BHE}}$ | A_0 | Characteristics |
|-------------------------|--------------|---------------------------------|
| 0 | 0 | Whole word |
| 0 | 1 | Upper byte from/to odd address |
| 1 | 0 | Lower byte from/to even address |
| 1 | 1 | None |

I/O ports are addressed in the same manner as memory location. Even addressed bytes are transferred on the $\text{D}_7\text{--}\text{D}_0$ bus lines and odd addressed bytes on $\text{D}_{15}\text{--}\text{D}_8$.

The basic difference between the interrupt acknowledge cycle and a read cycle is that the interrupt acknowledge signal ($\overline{\text{INTA}}$) is asserted in place of the read ($\overline{\text{RD}}$) signal and the address bus is floated. (See Figure 6.) In the second of two successive $\overline{\text{INTA}}$ cycles, a byte of information is read from bus

lines D₇–D₀ as supplied by the interrupt system logic (i.e., 8259A Priority Interrupt Controller). This byte identifies the source (type) of the interrupt. It is multiplied by four and used as a pointer into an interrupt vector lookup table, as described earlier.

BUS TIMING—MEDIUM SIZE SYSTEMS

For medium size systems the MN/ \overline{MX} pin is connected to V_{SS} and the 8288 Bus Controller is added to the system as well as a latch for latching the system address, and a transceiver to allow for bus loading greater than the 8086 is capable of handling. Signals ALE, DEN, and DT/ \overline{R} are generated by the 8288 instead of the processor in this configuration although their timing remains relatively the same. The 8086 status outputs (\overline{S}_2 , \overline{S}_1 , and \overline{S}_0) provide type-of-cycle information and become 8288 inputs. This bus cycle information specifies read (code, data, or I/O), write (data or I/O), interrupt

acknowledge, or software halt. The 8288 thus issues control signals specifying memory read or write, I/O read or write, or interrupt acknowledge. The 8288 provides two types of write strobes, normal and advanced, to be applied as required. The normal write strobes have data valid at the leading edge of write. The advanced write strobes have the same timing as read strobes, and hence data isn't valid at the leading edge of write. The transceiver receives the usual DIR and \overline{G} inputs from the 8288's DT/ \overline{R} and DEN.

The pointer into the interrupt vector table, which is passed during the second INTA cycle, can derive from an 8259A located on either the local bus or the system bus. If the master 8259A Priority Interrupt Controller is positioned on the local bus, a TTL gate is required to disable the transceiver when reading from the master 8259A during the interrupt acknowledge sequence and software "poll".

ABSOLUTE MAXIMUM RATINGS*

Ambient Temperature Under Bias 0°C to 70°C
 Storage Temperature -65°C to +150°C
 Voltage on Any Pin with
 Respect to Ground -1.0V to +7V
 Power Dissipation 2.5W

NOTICE: This is a production data sheet. The specifications are subject to change without notice.

*WARNING: Stressing the device beyond the "Absolute Maximum Ratings" may cause permanent damage. These are stress ratings only. Operation beyond the "Operating Conditions" is not recommended and extended exposure beyond the "Operating Conditions" may affect device reliability.

D.C. CHARACTERISTICS (8086: $T_A = 0^\circ\text{C}$ to 70°C , $V_{CC} = 5\text{V} \pm 10\%$)

| TCHDTH | Direction Control Inactive Delay (Note 1) | | 30 | | 30 | | 30 | ns | |
| TCLGL | GT Active Delay | 0 | 85 | 0 | 38 | 0 | 50 | ns | |
| TCLGH | GT Inactive Delay | 0 | 85 | 0 | 45 | 0 | 50 | ns | |
| TRLRH | RD Width | 2TCLCL-75 | | 2TCLCL-40 | | 2TCLCL-50 | | ns | |
| TOLOH | Output Rise Time | | 20 | | 20 | | 20 | ns | |
| TOHOL | Output Fall Time | | 12 | | 12 | | 12 | ns | From 2.0V to 0.8V |

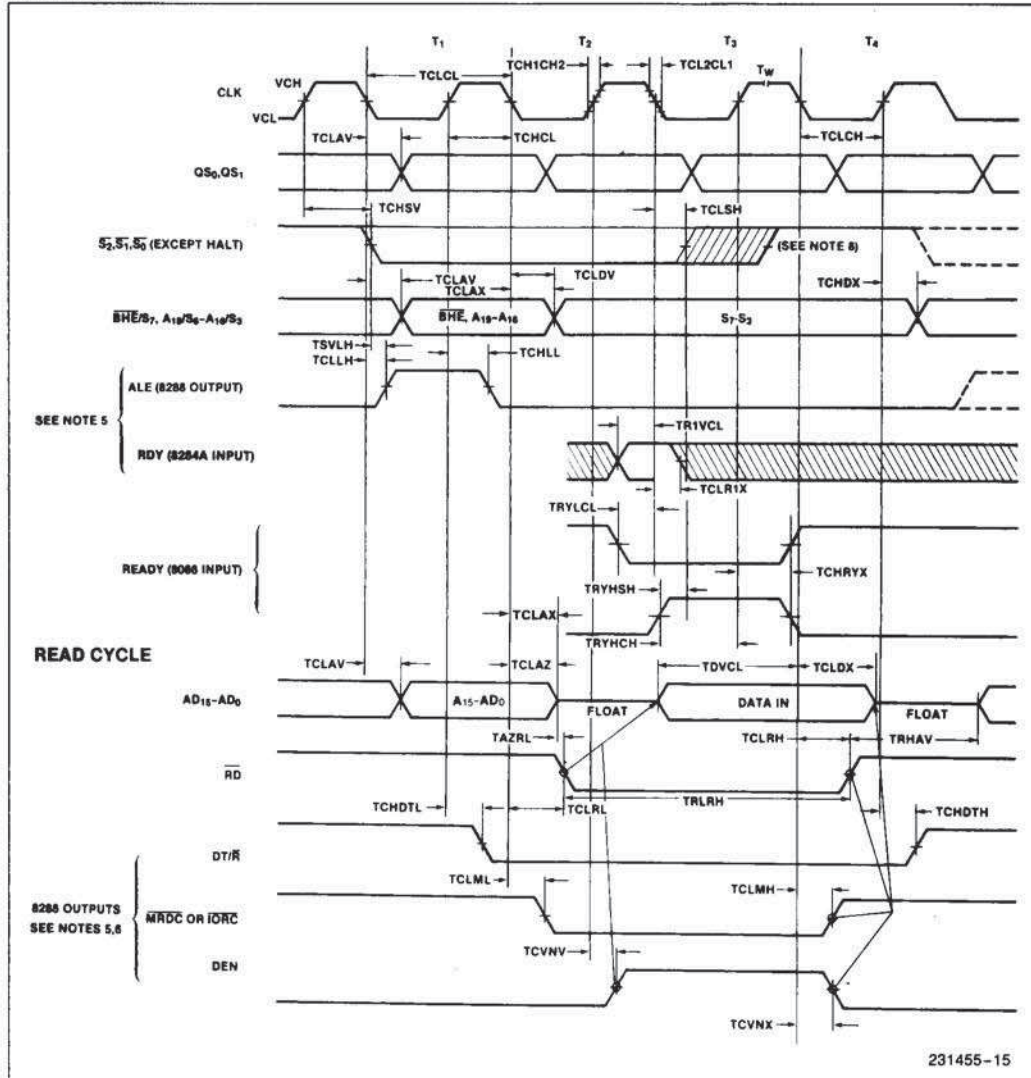

3

NOTES:

1. Signal at 8284A or 8288 shown for reference only.
2. Setup requirement for asynchronous signal only to guarantee recognition at next CLK.
3. Applies only to T3 and wait states.
4. Applies only to T2 state (8 ns into T3).

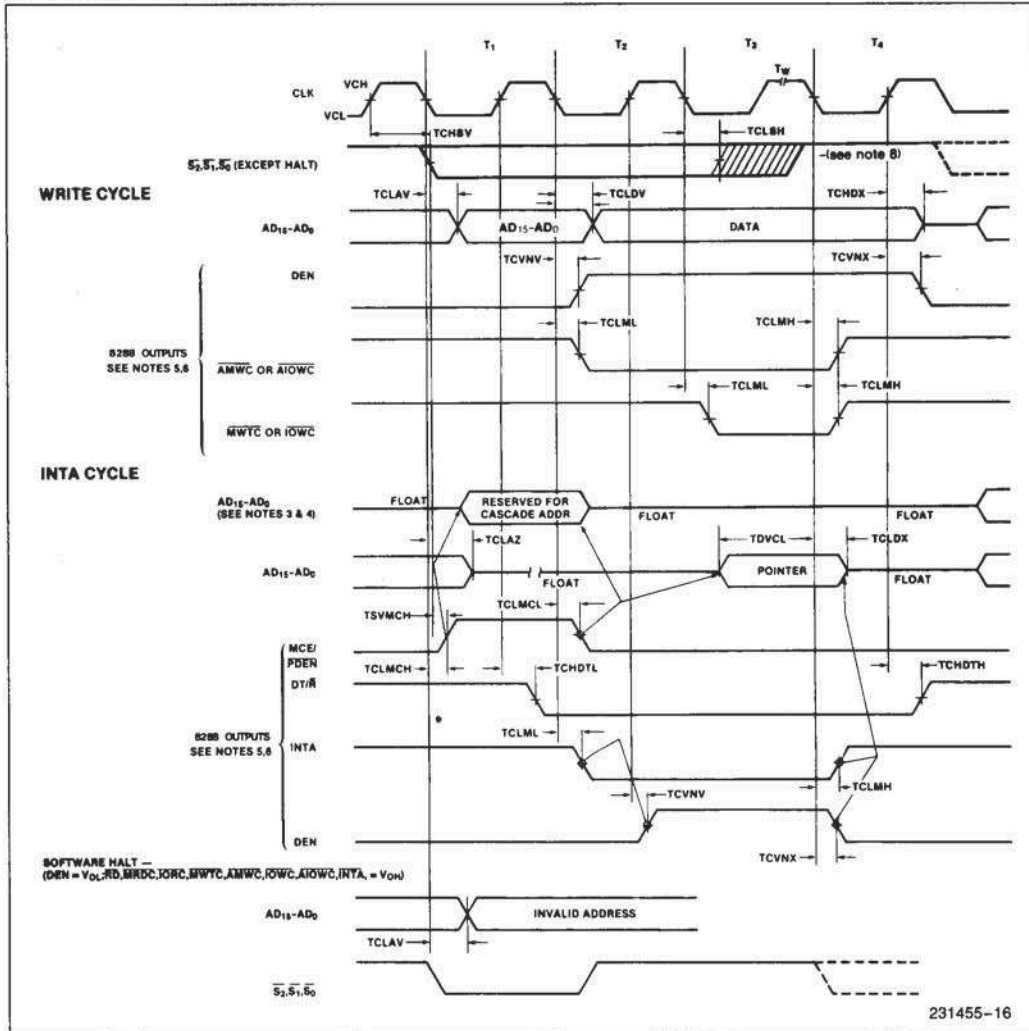

WAVEFORMS

MAXIMUM MODE

WAVEFORMS (Continued)

MAXIMUM MODE (Continued)

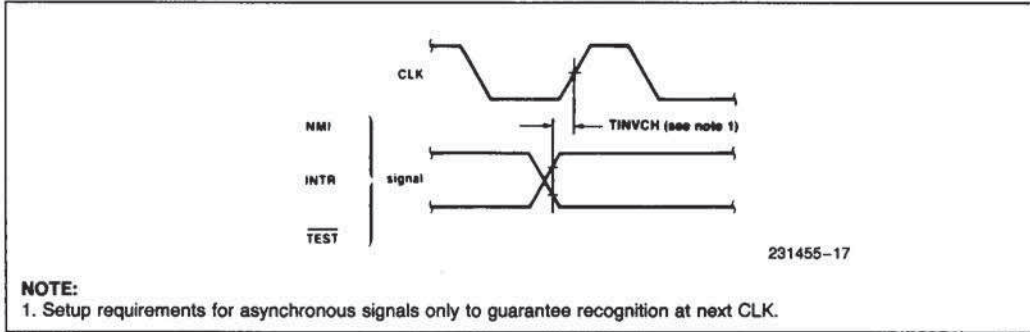

3

NOTES:

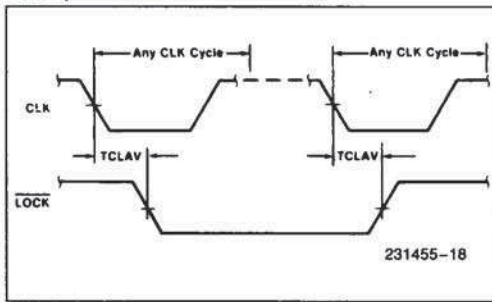

1. All signals switch between V_{OH} and V_{OL} unless otherwise specified.
2. RDY is sampled near the end of T_2 , T_3 , T_W to determine if T_W machine states are to be inserted.
3. Cascade address is valid between first and second INTA cycle.
4. Two INTA cycles run back-to-back. The 8086 LOCAL ADDR/DATA BUS is floating during both INTA cycles. Control for pointer address is shown for second INTA cycle.
5. Signals at 8284A or 8288 are shown for reference only.
6. The issuance of the 8288 command and control signals (\overline{MRDC} , \overline{MWTC} , \overline{AMWC} , \overline{IORC} , \overline{IOWC} , \overline{AIOWC} , \overline{INTA} and DEN) lags the active high 8288 CEN.
7. All timing measurements are made at 1.5V unless otherwise noted.
8. Status inactive in state just prior to T_4 .

| HLT = Halt | 1 1 1 1 0 1 0 0 | |
| WAIT = Wait | 1 0 0 1 1 0 1 1 | |
| ESC = Escape (to External Device) | 1 1 0 1 1 x x x | mod x x x r/m |
| LOCK = Bus Lock Prefix | 1 1 1 1 0 0 0 0 | |

NOTES:

AL = 8-bit accumulator
 AX = 16-bit accumulator
 CX = Count register
 DS = Data segment
 ES = Extra segment
 Above/below refers to unsigned value
 Greater = more positive;
 Less = less positive (more negative) signed values
 if d = 1 then "to" reg; if d = 0 then "from" reg
 if w = 1 then word instruction; if w = 0 then byte instruction
 if mod = 11 then r/m is treated as a REG field
 if mod = 00 then DISP = 0*, disp-low and disp-high are absent
 if mod = 01 then DISP = disp-low sign-extended to 16 bits, disp-high is absent
 if mod = 10 then DISP = disp-high; disp-low
 if r/m = 000 then EA = (BX) + (SI) + DISP
 if r/m = 001 then EA = (BX) + (DI) + DISP
 if r/m = 010 then EA = (BP) + (SI) + DISP
 if r/m = 011 then EA = (BP) + (DI) + DISP
 if r/m = 100 then EA = (SI) + DISP
 if r/m = 101 then EA = (DI) + DISP
 if r/m = 110 then EA = (BP) + DISP*
 if r/m = 111 then EA = (BX) + DISP
 DISP follows 2nd byte of instruction (before data if required)
 *except if mod = 00 and r/m = 110 then EA = disp-high; disp-low.

DATA SHEET REVISION REVIEW

The following list represents key differences between this and the -004 data sheet. Please review this summary carefully.

1. The Intel 8086 implementation technology (HMOS) has been changed to (HMOS-III).
2. Delete all "changes from 1985 Handbook Specification" sentences.

if s w = 01 then 16 bits of immediate data form the operand
 and
 if s w = 11 then an immediate data byte is sign extended to form the 16-bit operand
 if v = 0 then "count" = 1; if v = 1 then "count" in (CL)
 x = don't care
 z is used for string primitives for comparison with ZF FLAG

SEGMENT OVERRIDE PREFIX

0 0 1 reg 1 1 0

REG is assigned according to the following table:

| 16-Bit (w = 1) | 8-Bit (w = 0) | Segment |
|----------------|---------------|---------|
| 000 AX | 000 AL | 00 ES |
| 001 CX | 001 CL | 01 CS |
| 010 DX | 010 DL | 10 SS |
| 011 BX | 011 BL | 11 DS |
| 100 SP | 100 AH | |
| 101 BP | 101 CH | |
| 110 SI | 110 DH | |
| 111 DI | 111 BH | |

Instructions which reference the flag register file as a 16-bit object use the symbol FLAGS to represent the file:
 FLAGS = X:X:X:(OF):(DF):(IF):(TF):(SF):(ZF):X:(AF):X:(PF):X:(CF)
