

CC025 Triple-Output-Series Power Modules: 18 Vdc to 36 Vdc Input; 25 W

The CC025 Triple-Output-Series Power Modules use advanced, surface-mount technology and deliver high-quality, compact, dc-dc conversion at an economical price.

Features

- Small size: 71.1 mm x 61.0 mm x 12.7 mm (2.80 in. x 2.40 in. x 0.50 in.)
- Low output noise
- Industry-standard pinout
- Metal case
- 2:1 input voltage range
- Remote on/off (positive logic)
- *UL** Recognized, *CSA*† Certified, and VDE Licensed
- Within FCC and CISPR Class A radiated limits

Applications

- Distributed power architectures
- Telecommunications

Options

- Isolated case ground pin
- Short pins: 2.79 mm ± 0.25 mm (0.110 in. ± 0.010 in.)
- Heat sink available for extended operation
- Negative logic remote on/off

Description

The CC025 Triple-Output-Series Power Modules are dc-dc converters that operate over an input voltage range of 18 Vdc to 36 Vdc and provide three outputs. These modules offer extremely low noise levels with industry-standard pinouts in a small footprint. Each highly reliable and efficient unit features remote on/off and current limit.

The maximum total output power of the CC025 Triple-Output-Series Power Modules is limited to 25 W. The main output (V_{O1}) is designed to deliver the entire 25 W. The auxiliary outputs (V_{O2} and V_{O3}) can provide a total of 22.5 W as long as the total output power does not exceed 25 W.

Efficiency greater than 80%, a wide operating temperature range, and a metal case are additional features of these modules.

* *UL* is a registered trademark of Underwriters Laboratories, Inc.

† *CSA* is a registered trademark of Canadian Standards Association.

Absolute Maximum Ratings

Stresses in excess of the absolute maximum ratings can cause permanent damage to the device. These are absolute stress ratings only. Functional operation of the device is not implied at these or any other conditions in excess of those given in the operations sections of the data sheet. Exposure to absolute maximum ratings for extended periods can adversely affect device reliability.

Parameter	Symbol	Min	Max	Unit
Input Voltage Continuous	V_i	—	50	V
I/O Isolation Voltage:				
dc	—	—	500	V
Transient (1 minute)	—	—	850	V
Operating Case Temperature	T_c	-40	100	°C
Storage Temperature	T_{stg}	-55	125	°C

Electrical Specifications

Unless otherwise indicated, specifications apply to all modules over all operating input voltage, resistive load, and temperature conditions.

Table 1. Input Specifications

Parameter	Symbol	Min	Typ	Max	Unit
Operating Input Voltage	V_i	18	28	36	Vdc
Maximum Input Current ($V_i = 0$ V to 36 V; $I_o = I_{o,max}$; see Figure 1.)	$I_{i,max}$	—	—	3.0	A
Inrush Transient	i^2t	—	—	0.2	A ² s

Input Ripple Rejection (120 Hz)	—	—	60	—	dB

Fusing Considerations

CAUTION: This power module is not internally fused. An input line fuse must always be used.

This encapsulated power module can be used in a wide variety of applications, ranging from simple stand-alone operation to an integrated part of a sophisticated power architecture. To preserve maximum flexibility, internal fusing is not included; however, to achieve maximum safety and system protection, always use an input line fuse. The safety agencies require a normal-blow, dc fuse with a maximum rating of 5 A in series with the ungrounded input lead. Based on the information provided in this data sheet on inrush energy and maximum dc input current, the same type of fuse with a lower rating can be used. Refer to the fuse manufacturer's data for further information.

8-749(C).c

Note: All measurements are taken at the module terminals. When socketing, place Kelvin connections at module terminals to avoid measurement errors due to socket contact resistance.

$$\eta = \frac{\sum_{j=1}^n | [V_{Oj}(+) - V_{COM}] I_{Oj} |}{[V_{I}(+) + (-V_{I}(-))] I_i} \times 100$$

Figure 20. Triple Output Voltage and Efficiency Measurement Test Setup

Design Considerations

Input Source Impedance

The power module should be connected to a low ac-impedance input source. Highly inductive source impedances can affect the stability of the power module. A 33 µF electrolytic capacitor (ESR < 0.7 Ω at 100 kHz) mounted close to the power module helps to ensure the stability of the unit.

Safety Considerations

For safety-agency approval of the system in which the power module is used, the power module must be installed in compliance with the spacing and separation requirements of the end-use safety agency standard, i.e., UL-1950, CSA 22.2-950, and EN60950.

For the converter output to be considered meeting the requirements of safety extra-low voltage (SELV), the input must meet SELV requirements.

If the input meets extra-low voltage (ELV) requirements, then the converter's output is considered ELV.

The input to these units is to be provided with a maximum 5 A normal-blow fuse in the ungrounded lead.

Feature Descriptions

Output Overvoltage Clamp

The output overvoltage clamp consists of control circuitry, independent of the primary regulation loop, that monitors the voltage on the output terminals. The control loop of the clamp has a higher voltage set point than the primary loop (see Feature Specifications table). This provides a redundant voltage control that reduces the risk of output overvoltage.

Current Limit

To provide protection in a fault (output overload) condition, the unit is equipped with internal current-limiting circuitry. At the point of current-limit inception, the unit shifts from voltage control to current control. If the output voltage is pulled very low during a severe fault, the current-limit circuit can exhibit either foldback or tailout characteristics (output current decrease or increase). The unit operates normally once the output current is brought back into its specified range.

Output Voltage Set-Point Adjustment

The output voltage adjustment feature provides the capability of increasing or decreasing the output voltage set point of a module. This can be accomplished by using an external resistor connected between the TRIM pin and either the $V_{O1}(+)$ or common pins. With an external resistor between the TRIM and common pins (R_{adj-up}), the output voltage set point ($V_{O, adj}$) increases.

$$R_{adj-up} = \left(\frac{42.35}{V_{O, adj} - V_{O, nom}} \right) k^{3/4}$$

Note: The output voltage adjustment range must not exceed 110% of the nominal output voltage between the $V_{O1}(+)$ and common terminals.

With an external resistor connected between the TRIM and $V_{O1}(+)$ pins ($R_{adj-down}$), the output voltage set point ($V_{O, adj}$) decreases.

$$R_{adj-down} = \left(\frac{(V_{O, adj} - 2.5) \times 16.94}{V_{O, nom} - V_{O, adj}} \right) k^{3/4}$$

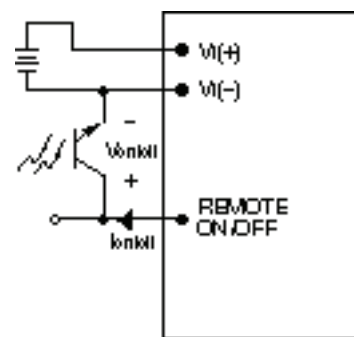

Note: The output voltage adjustment must be 90% or more of the nominal output voltage between the $V_{O1}(+)$ and common terminals.

Remote On/Off

Two remote on/off options are available. Positive logic remote on/off turns the module on during a logic high voltage on the REMOTE ON/OFF pin, and off during a logic low. Negative logic remote on/off, suffix code "1," turns the module off during a logic high and on during a logic low.

To turn the power module on and off, the user must supply a switch to control the voltage between the on/off terminal and the $V_I(-)$ terminal ($V_{on/off}$). The switch can be an open collector or equivalent (see Figure 21). A logic low is $V_{on/off} = 0$ V to 1.2 V. The maximum $I_{on/off}$ during a logic low is 1 mA. The switch should maintain a logic low-voltage while sinking 1 mA.

During a logic high, the maximum $V_{on/off}$ generated by the power module is 10 V. The maximum allowable leakage current of the switch at $V_{on/off} = 10$ V is 50 μ A.

8-758(C).a

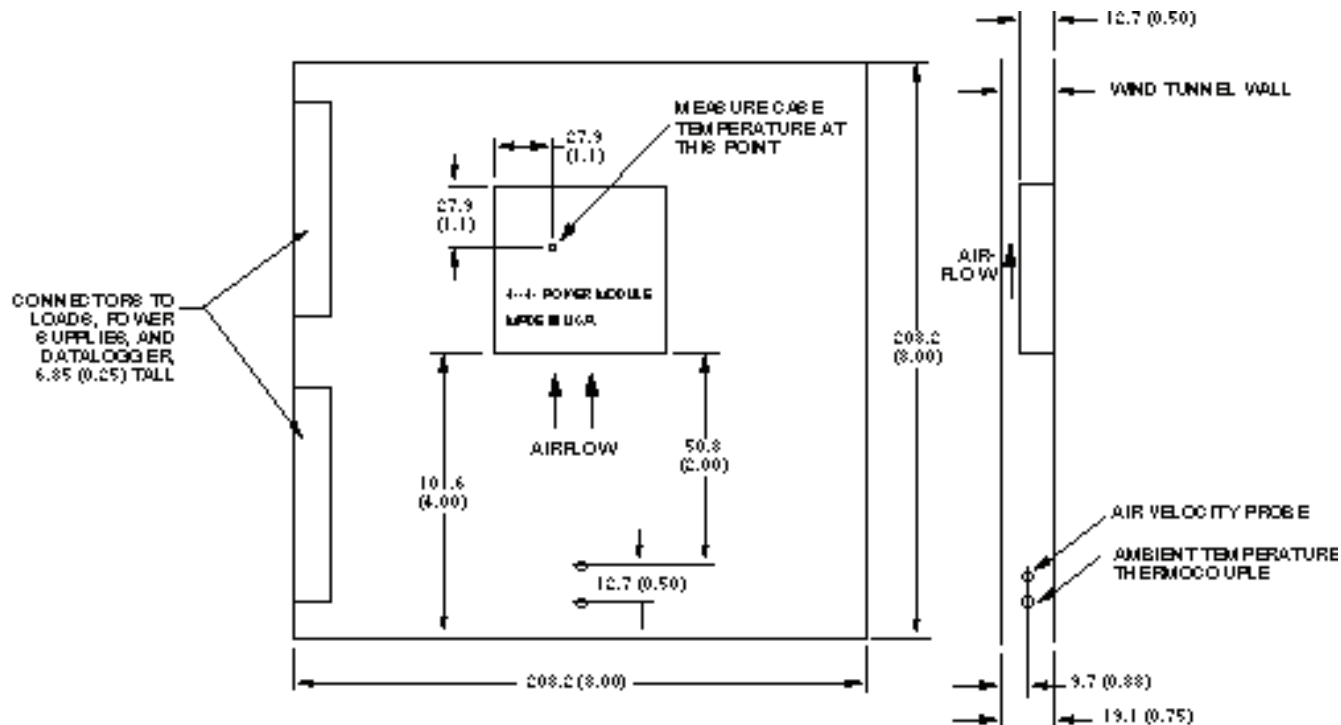

Figure 21. Remote On/Off Implementation

CAUTION: To avoid damaging the module or external circuitry, the $V_I(-)$ pin must be connected to the $-48pV$ source before or simultaneously to connecting the ON/OFF pin to the $-48pV$ source (either directly or through the external on/off circuitry).

Grounding Considerations

For modules without the isolated case ground pin option, the case is internally connected to the $V_I(-)$ pin. For modules with the isolated case ground pin, the $V_I(-)$ is not connected to the case.

Thermal Considerations

Note: Dimensions are in millimeters and (inches). Drawing is not to scale.

8-866(C).b

Figure 22. Thermal Test Setup

The 25 W triple output power modules are designed to operate in a variety of thermal environments. As with any electronic component, sufficient cooling must be provided to ensure reliable operation. Heat dissipating components inside the module are thermally coupled to the case to enable heat removal by conduction, convection, and radiation to the surrounding environment.

The thermal data presented is based on measurements taken in a wind tunnel. The test setup shown in Figure 22 was used to collect data. Actual performance can vary depending on the particular application environment.

Thermal Considerations (continued)

Basic Thermal Performance

The maximum operating temperature of the CC025 Triple-Output-Series Power Modules at a given operating condition can be predicted by combining the power dissipation curves (Figures 23 through 27), the power derating curve (Figure 28), and the thermal resistance curve (Figure 29).

Use Figures 23 through 28 and the steps below to predict the safe operating region for many different operating and environmental conditions.

1. Calculate the total output power.

$$P_{\text{Ototal}} = (I_{\text{O1}} \times V_{\text{O1}}) + (I_{\text{O2}} \times V_{\text{O2}}) + (I_{\text{O3}} \times V_{\text{O3}})$$

2. Use P_{Ototal} with the appropriate figure (Figure 23 or 25) to determine the fixed losses (P_{P}) associated with operating at P_{Ototal} . These losses are independent of which output the load is being drawn from.
3. Use the desired output current (I_{O1}) with Figure 25 to determine P_{S1} , which is the additional power being dissipated due to loading of the main output.
4. Repeat Step 3 for outputs 2 and 3 using the appropriate figure (Figure 23 or 27) to determine P_{S2} and P_{S3} , which is the power dissipated due to loading of the auxiliary outputs.
5. Find the total power dissipated (P_{Dtotal}) by adding the four power dissipations obtained in Steps 2 through 4.

$$P_{\text{Dtotal}} = P_{\text{P}} + P_{\text{S1}} + P_{\text{S2}} + P_{\text{S3}}$$

6. Use the estimated total power dissipated (P_{Dtotal}) along with Figure 28 to determine the maximum ambient temperature allowable for a given air velocity.

For example, consider the CC025ABK power module operating with 27 V input and output currents $I_{\text{O1}} = 2.5 \text{ A}$, $I_{\text{O2}} = 0.5 \text{ A}$, $I_{\text{O3}} = 0.5 \text{ A}$.

The total output power (P_{Ototal}) is 24.5 W. The total power dissipation is $P_{\text{Dtotal}} = 4.86 \text{ W}$, which is obtained by adding:

$$\begin{aligned} P_{\text{P}} &= 4.5 \text{ W (from Figure 23)} \\ P_{\text{S1}} &= 0.22 \text{ W (from Figure 25)} \\ P_{\text{S2}} &= 0.07 \text{ W (from Figure 23)} \\ P_{\text{S3}} &= 0.07 \text{ W (from Figure 23)} \end{aligned}$$

Figure 28 shows that in natural convection the maximum operating ambient temperature for this module is approximately 66 °C.

Keep in mind that the procedure above provides approximations of the temperature and air velocities required to keep the case temperature below its maximum rating. The maximum case temperature, as monitored at the point shown in Figure 22, should be maintained at 100 °C or less under all conditions.

Air Velocity

The air velocity required to maintain a desired maximum case temperature for a given power dissipation and ambient temperature can be calculated using Figure 28 and the following equation:

$$\theta_{\text{CA}} = \frac{T_{\text{Cmax}} - T_{\text{A}}}{P_{\text{Dtotal}}}$$

where:

- n θ_{CA} is the thermal resistance from case-to-ambient air (°C/W)
- n T_{Cmax} is the desired maximum case temperature (°C)
- n T_{A} is the ambient inlet temperature (°C)
- n P_{Dtotal} is the total power dissipated by the module (W) at the desired operating condition

For example, to maintain a maximum case temperature of 85 °C with an ambient inlet temperature of 65 °C and a power dissipation of 4.86 W, the thermal resistance is:

$$\theta_{\text{CA}} \leq \frac{85 \text{ °C} - 65 \text{ °C}}{4.86 \text{ W}} = 4.1 \text{ °C/W}$$

This corresponds to an airflow greater than 0.38 ms⁻¹ (75 fpm) in Figure 28.

Use of Heat Sinks and Cold Plates

The CC025 Triple-Output-Series case includes through-threaded M3 x 0.5 mounting holes allowing attachment of heat sinks or cold plates from either side of the module. The mounting torque must not exceed 0.56 N/m (5 in.-lb).

The following thermal model can be used to determine the required thermal resistance of the sink to provide the necessary cooling:

where Pd is the power dissipated by the module, theta cs represents the interfacial contact resistance between the module and the sink, and theta SA is the sink-to-ambient thermal impedance (°C/W). For thermal greases or foils, a value of theta cs = 0.1 °C/W to 0.3 °C/W is typical.

The required theta SA is calculated from the following equation:

$$\theta_{SA} = \frac{T_C - T_A}{P_{dtotal}} - \theta_{cs}$$

Note that this equation assumes that all dissipated power must be shed by the sink. Depending on the user-defined application environment, a more accurate model including heat transfer from the sides and rear of the module can be used. This equation provides a conservative estimate in such instances.

For further thermal information on these modules, refer to the *Thermal Management for CC-, CW, DC, DW-Series 25 W to 30 W Board-Mounted Power Modules* Technical Note.

Outline Diagram

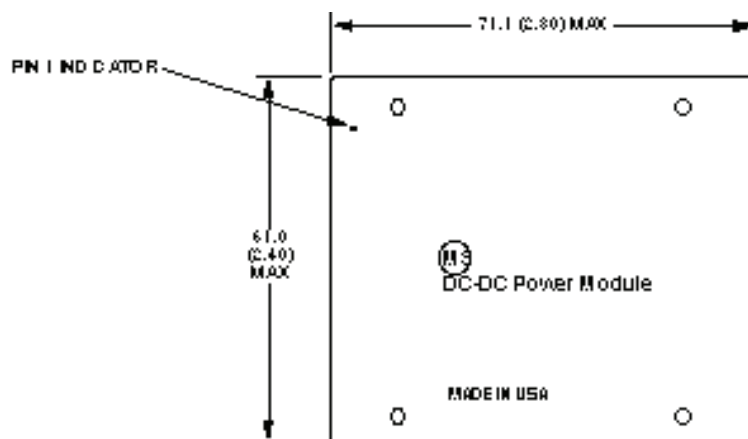

Dimensions are in millimeters and (inches).

Copper paths must not be routed beneath the power module standoffs.

Tolerances: $x.x \pm 0.5$ mm (0.02 in.), $x.xx \pm 0.25$ mm (0.010 in.).

Note: For standard modules, $V_i(-)$ is internally connected to the case and the CASE pin is not present. If the CASE GROUND pin is chosen, device code suffix 7, then $V_i(-)$ is not connected to the case and the CASE GROUND pin is floating.
