Z86C61/62/96

CMOS Z8 MICROCONTROLLER

FEATURES

Device	ROM (KB)	RAM* (Bytes)	I/O Lines
Z86C61	16	236	32
Z86C62	16	236	52
Z86C96	16	236	52

Note: *General-Purpose

- 3.0V to 5.5V Operating Range
- Low Power Consumption: 200 mW (max)
- Fast Instruction Pointer: 0.75 µs @ 16 MHz
- Two Standby Modes: STOP and HALT
- Full-Duplex UART
- All Digital Inputs are TTL Levels
- Auto Latches
- RAM and ROM Protect
- Two Programmable 8-Bit Counter/Timers,
- Each with 6-Bit Programmable Prescaler
- Six Vectored, Priority Interrupts from Eight Different Sources
- Clock Speeds: 16 and 20 MHz
- On-Chip Oscillator that Accepts a Crystal, Ceramic Resonator, LC, or External Clock Drive

GENERAL DESCRIPTION

The Z86C61/62/96 microcontroller is a member of the Z8 single-chip microcontroller family with 16 KB of ROM and 236 bytes of RAM. The Z86C96 is ROMless.

The Z86C61 is offered in 40-pin DIP and 44-pin PLCC style packages, however, the ROMless pin option is available on the 44-pin version only. The Z86C62/96 is offered in 64-pin DIP and 68-pin PLCC style packages. A ROMless pin option enables these MCUs to address both external memory and preprogrammed ROM, making them well-suited for high-volume applications or where code flexibility is required.

With 16 KB of ROM and 236 bytes of general-purpose RAM, these low-cost, low power consumption CMOS Z86C61/62/96 MCUs offer fast execution, efficient use of memory, sophisticated interrupts, input/output bit manipulation capabilities, and easy hardware/software system expansion.

The Z86C61/62/96 architecture is characterized by Zilog's 8-bit microcontroller core. The device offers a flexible I/O scheme, an efficient register and address space structure, multiplexed capabilities between address/data, I/O, and a number of ancillary features that are useful in many industrial and advanced scientific applications.

For applications which demand powerful I/O capabilities, the Z86C61 fulfills this with 32 pins dedicated to input and output. These lines are grouped into four ports with eight lines each. The Z86C62/96 has 52 pins for input and output, and these lines are grouped into six, 8-bit ports and one 4-bit port. Each port is configurable under software control to provide timing, status signals, serial or parallel I/O with or without handshake, and an address/data bus for interfacing external memory.

There are three basic address spaces available to support this configuration: Program Memory, Data Memory, and 236 General-Purpose Registers.

GENERAL DESCRIPTION (Continued)

To unburden the program from coping with the real-time tasks, such as counting/timing and serial data communication, the Z86C61/62/96 offers two on-chip counter/timers with a large number of user selectable modes, and an on-board UART (Figures 1, 2, and 3).

Notes: All Signals with a preceding front slash, "/", are active Low. For example B//W (WORD is active Low); /B/W (BYTE is active Low, only).

Power connections follow conventional descriptions below:

Connection	Circuit	Device
Power	V_{CC}	V_{DD}
Ground	GND	V_{SS}

ABSOLUTE MAXIMUM RATINGS

Sym	Description	Min	Max	Units
V_{CC}	Supply Voltage*	–0.3	+7.0	V
T_{STG}	Storage Temp	–65	+150	C
T_A	Oper Ambient Temp	†	†	

Notes:
*Voltages on all pins with respect to GND.
†See ordering information

Stresses greater than those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; operation of the device at any condition above those indicated in the operational sections of these specifications is not implied. Exposure to absolute maximum rating conditions for an extended period may affect device reliability.

STANDARD TEST CONDITIONS

The characteristics listed below apply for standard test conditions as noted. All voltages are referenced to GND. Positive current flows into the referenced pin (Figure 4).

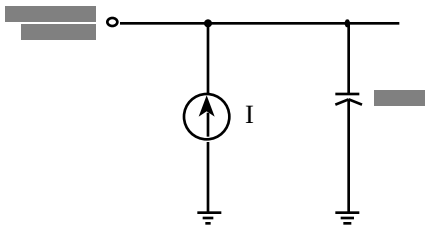

Figure 8. Test Load Diagram

11	TdRDY0d(DAV)	RDY rise to DAV fall Delay	115		115		OUT

PIN FUNCTIONS

R//RL (input, active Low). This pin when connected to GND disables the internal ROM and forces the device to function as a Z86C96 ROMless Z8. (Note: When left unconnected or pulled High to VCC the part functions as a normal Z86C61/62 ROM version.) This pin is only available on the 44-pin version of the Z86C61, and both versions of the Z86C62.

/DS (output, active Low). Data Strobe is activated once for each external memory transfer. For a READ operation, data must be available prior to the trailing edge of /DS. For WRITE operations, the falling edge of /DS indicates that output data is valid.

/AS (output, active Low). Address Strobe is pulsed once at the beginning of each machine cycle. Address out-put is through Port 1 for all external programs. Memory address transfers are valid at the trailing edge of /AS. Under program control, /AS can be placed in the high-impedance state along with Ports 0 and 1, Data Strobe, and Read/Write.

XTAL1, XTAL2 Crystal 1, Crystal 2 (time-based input and output, respectively). These pins connect a parallel-resonant crystal, ceramic resonator, LC, or any external single-phase clock to the on-chip oscillator and buffer.

R//W (output, write Low). The Read/Write signal is Low when the MCU is writing to the external program or data memory.

/RESET (input, active Low). To avoid asynchronous and noisy reset problems, the Z86C61/62/96 is equipped with a reset filter of four external clocks (4TpC). If the external /RESET signal is less than 4TpC in duration, no reset occurs.

On the fifth clock after the /RESET is detected, an internal RST signal is latched and held for an internal register count of 18 external clocks, or for the duration of the external /RESET, whichever is longer. During the reset cycle, /DS is held active Low while /AS cycles at a rate of TpC/2. When /RESET is deactivated, program execution begins at location 000C (HEX). Reset time must be held Low for 50 ms, or until VCC is stable, whichever is longer.

/P0DS Port 0 Data Strobe (output, active Low). Signal used to emulate Port 0 when in ROMless mode.

/P1DS Port 1 Data Strobe (output, active Low). Signal used to emulate Port 1 when in ROMless mode.

/DTIMERS Disable Timers (input, active Low). All timers are stopped by the Low level at this pin. This pin has an internal pull up resistor.

SCLK (output). System clock pin.

/SYNC Instruction SYNC Signal (output, active Low). This signal indicates the last clock of the current executing instruction.

Port 0 (P07-P00). Port 0 is an 8-bit, nibble programmable, bidirectional, TTL compatible port. These eight I/O lines can be configured under software control as a nibble I/O port, or as an address port for interfacing external memory. When used as an I/O port, Port 0 may be placed under handshake control. In this configuration, Port 3, lines P32 and P35 are used as the handshake control /DAV0 and RDY0 (Data Available and Ready). Handshake signal assignment is dictated by the I/O direction of the upper nibble P07-P04. The lower nibble must have the same direction as the upper nibble to be under handshake control.

For external memory references, Port 0 can provide address bits A11-A8 (lower nibble) or A15-A8 (lower and upper nibble) depending on the required address space. If the address range requires 12 bits or less, the upper nibble of Port 0 can be programmed independently as I/O while the lower nibble is used for addressing. If one or both nibbles are needed for I/O operation, they must be configured by writing to the Port 0 Mode register.

In ROMless mode, after a hardware reset, Port 0 lines are defined as address lines A15-A8, and extended timing is set to accommodate slow memory access. The initialization routine includes reconfiguration to eliminate this extended timing mode (Figure 14).

PIN FUNCTIONS (Continued)

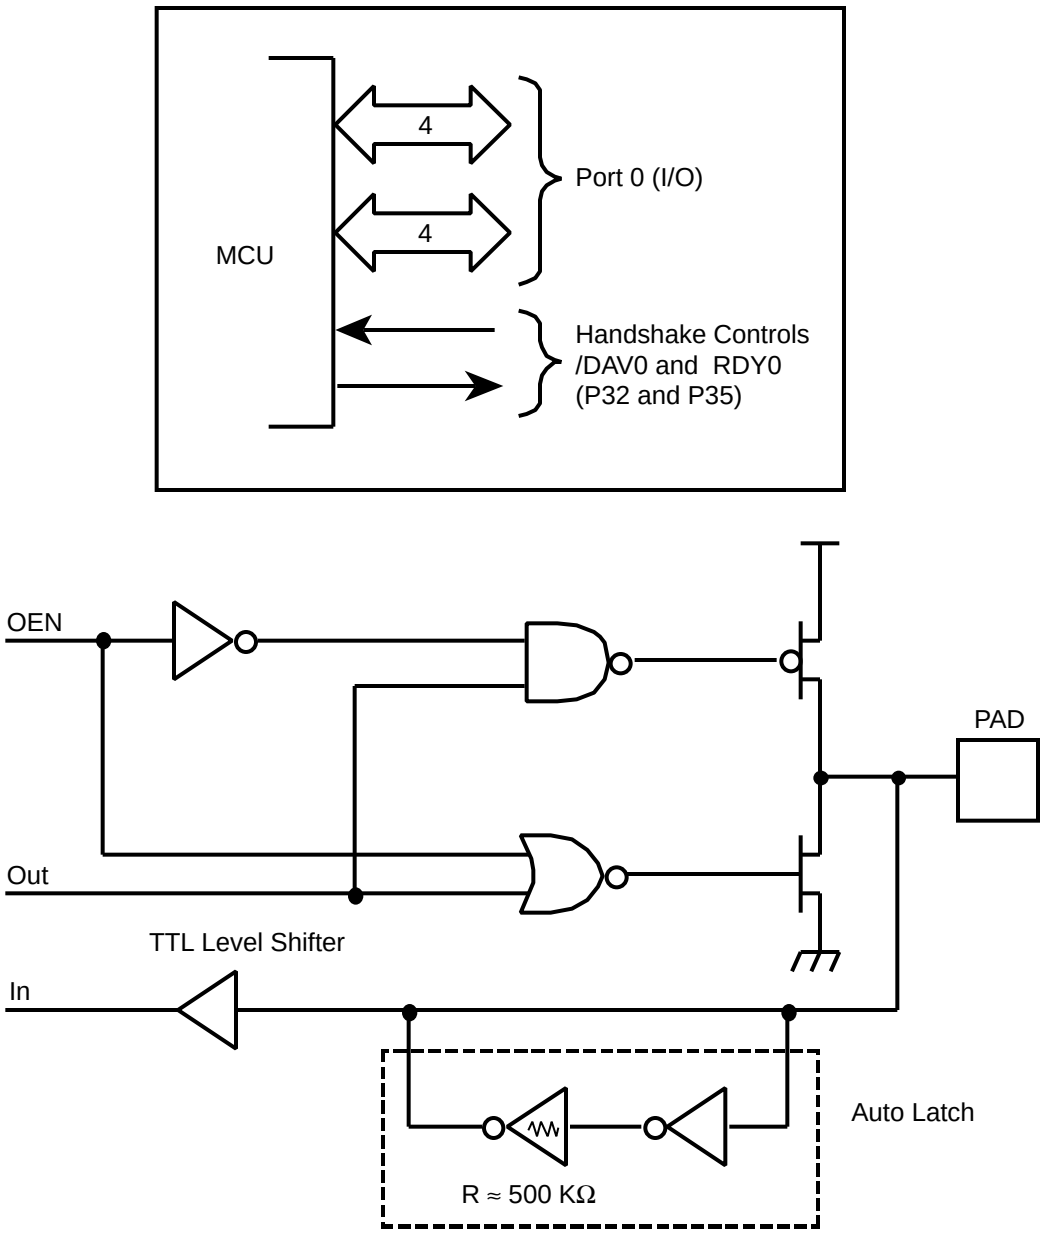

Figure 13. Port 0 Configuration

Port 1 (P17-P10). Port 1 is an 8-bit, byte programmable, bidirectional, TTL compatible port. It has multiplexed Address (A7-A0) and Data (D7-D0) ports. For Z86C61/62/96, these eight I/O lines can be programmed as Input or Output lines or can be configured under software control as an address/data port for interfacing external memory. When used as an I/O port, Port 1 may be placed under handshake control. In this configuration, Port 3 line P33 and P34 are used as the handshake controls RDY1 and /DAV1.

Memory locations greater than 16,384 are referenced through Port 1. To interface external memory, Port 1 must be programmed for the multiplexed Address/Data mode. If more than 256 external locations are required, Port 0 must output the additional lines.

Port 1 can be placed in high-impedance state along with Port 0, /AS, /DS, and R//W, allowing the microcontroller to share common resources in multiprocessor and DMA applications. Data transfers can be controlled by assigning P33 as a Bus Acknowledge input, and P34 as a Bus request output (Figure 14).

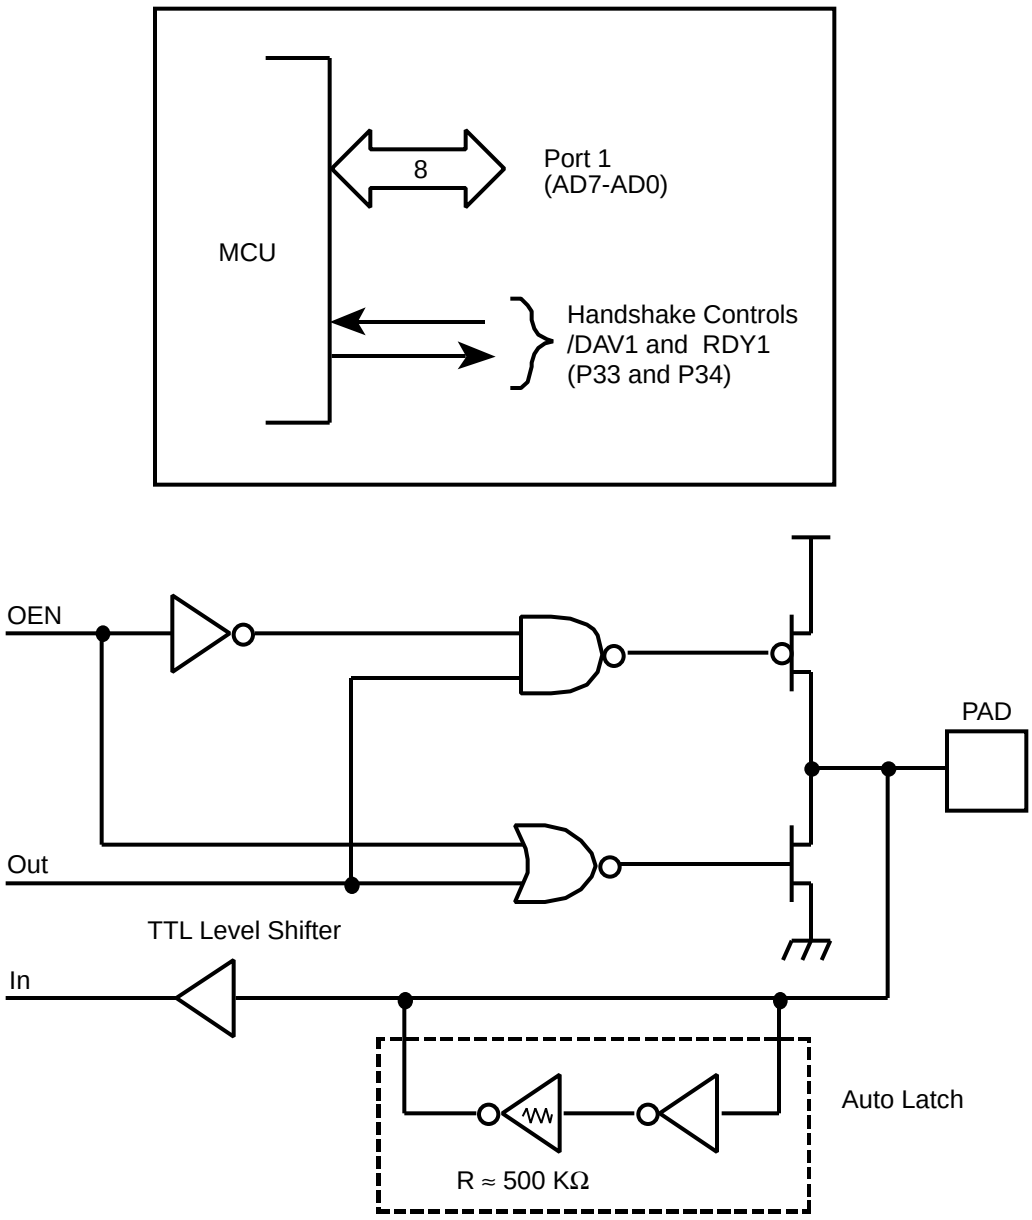

Figure 14. Port 1 Configuration

PIN FUNCTIONS (Continued)

Port 2 (P27-P20). Port 2 is an 8-bit, bit programmable, bi-directional, CMOS-compatible port. Each of these eight I/O lines can be independently programmed as an input or output or globally as an open-drain output. Port 2 is always available for I/O operation. When used as an I/O port, Port 2 may be placed under handshake control. In this configuration, Port 3 lines P31 and P36 are used as the handshake control lines /DAV2 and RDY2. The handshake signal assignment for Port 3 lines P31 and P36 is dictated by the direction (input or output) assigned to P27 (Figure 15).

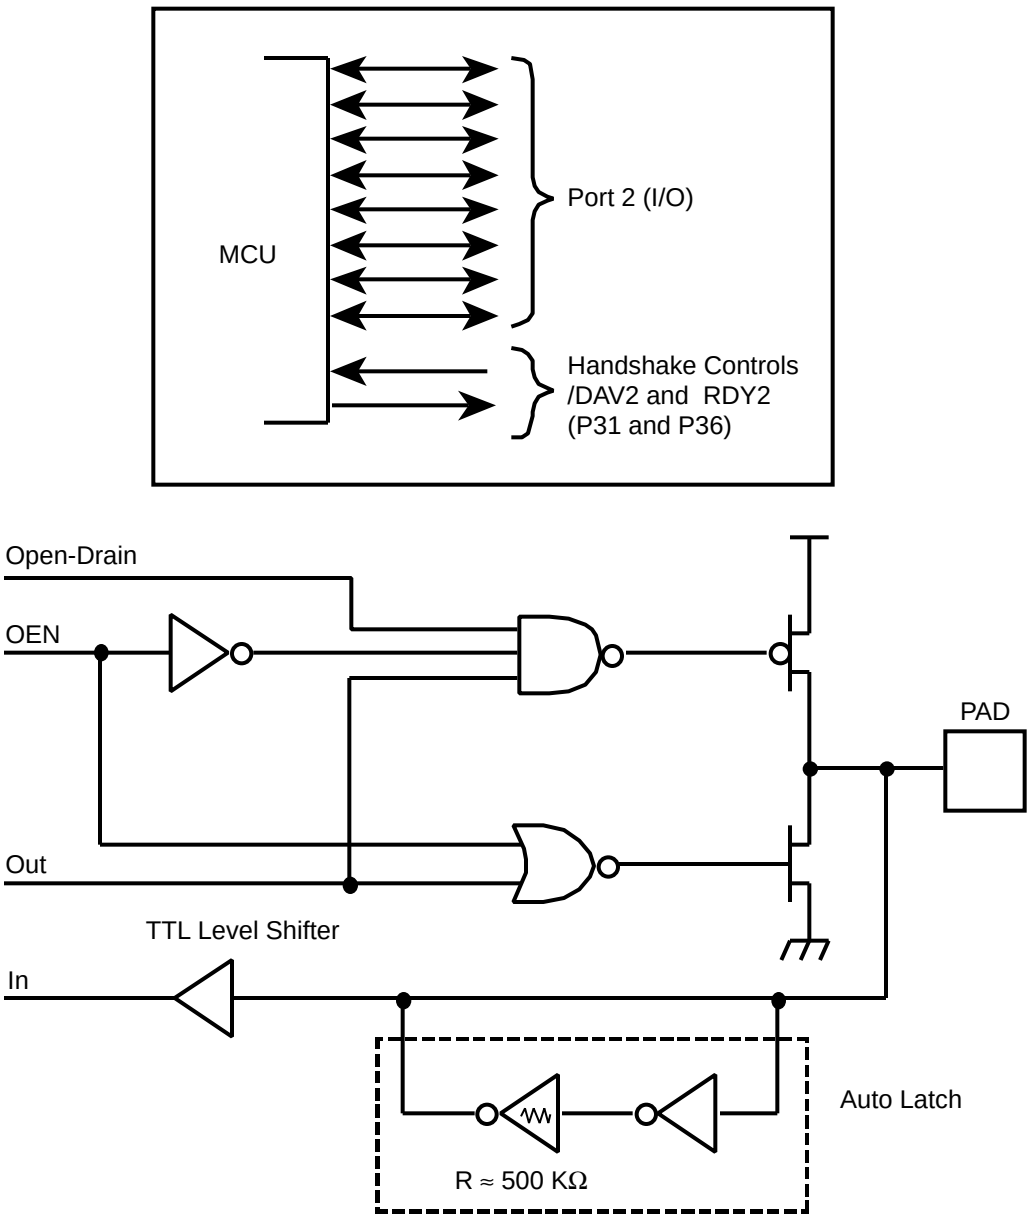

Figure 15. Port 2 Configuration

Port 3 (P37-P30). Port 3 is an 8-bit, CMOS-compatible four-fixed input and four-fixed output port. These eight I/O lines have four-fixed (P33-P30) input and four-fixed (P37-P34) output ports. Port 3, when used as serial I/O, are programmed as serial in and serial out, respectively (Figure 16).

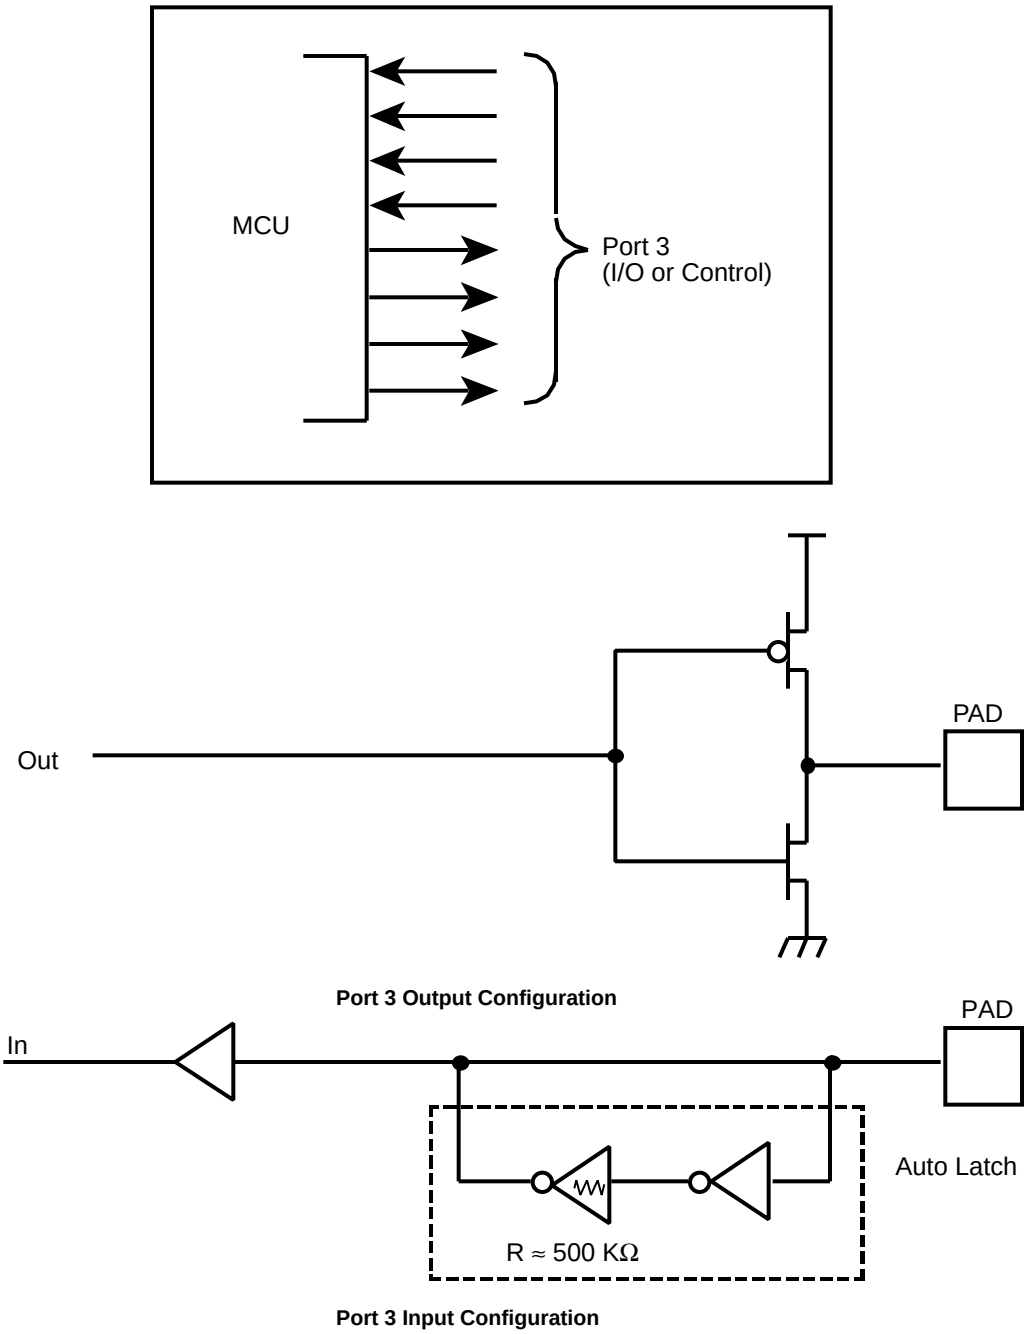

Figure 16. Port 3 Configuration

PIN FUNCTIONS (Continued)

Port 3 can be configured under software control to provide the following control functions: handshake for Ports 0 and 2 (/DAV and RDY); four external interrupt request signals (IRQ3-IRQ0); timer input and output signals (T_{IN} and T_{OUT}), and Data Memory Select (/DM).

Table 6. Port 3 Pin Assignments

Pin	I/O	CTC1	Int.	P0 HS	P1 HS	P2 HS	UART	Ext
P30	IN		IRQ3				Serial In	
P31	IN	T_{IN}	IRQ2			D/R		
P32	IN		IRQ0	D/R				
P33	IN		IRQ1		D/R			
P34	OUT				R/D			DM
P35	OUT			R/D				
P36	OUT	T_{OUT}				R/D		
P37	OUT						Serial Out	
T0			IRQ4					
T1			IRQ5					

Notes:
HS = Handshake Signals
D = Data Available
R = Ready

Uart Operation

Port 3 lines P30 and P37, can be programmed as serial I/O lines for full-duplex serial asynchronous receiver/transmitter operation. The bit rate is controlled by the Counter/Timer0.

The Z86C61/62/96 automatically adds a start bit and two stop bits to transmitted data (Figure 17). Odd parity is also available as an option. Eight data bits are always transmitted, regardless of parity selection. If parity is enabled, the eighth bit is the odd parity bit. An interrupt request (IRQ4) is generated on all transmitted characters.

Received data must have a start bit, eight data bits and at least one stop bit. If parity is on, bit 7 of the received data is replaced by a parity error flag. Received characters generate the IRQ3 interrupt request.

Note: UART function is only available in standard timing mode (i.e., P01M D5 = 0).

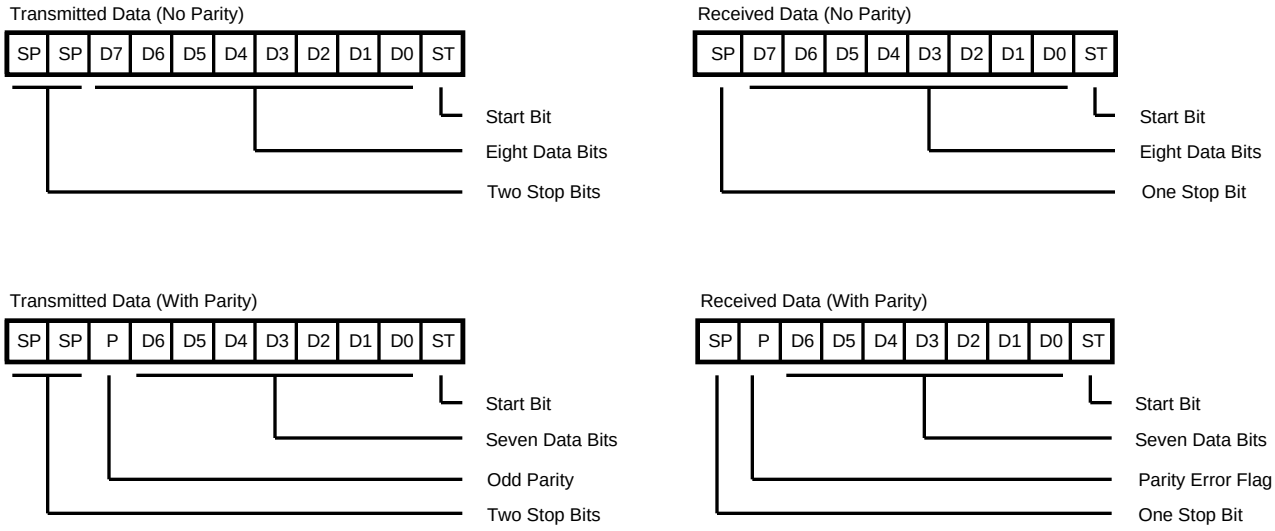

Figure 17. Serial Data Formats

PIN FUNCTIONS (Continued)

Port 4 (P47-P40). Port 4 is an 8-bit, bit programmable, bi-directional, CMOS-compatible port. Each of these eight I/O lines can be independently programmed as an input or output or globally as an open-drain output. Port 4 is always available for I/O operation (Figure 18). Port address (F)02.

Port 5 (P57-P50). Same as Port 4. Port address (F)04.

Port 6 (P63-P60). Same as Port 4. (Note: this is a 4-bit port, bits D3-D0.) Port address (F)07.

Auto Latch. The Auto Latch puts valid CMOS levels on all CMOS inputs that are not externally driven. This reduces excessive supply current flow in the input buffer when it is not being driven by any source.

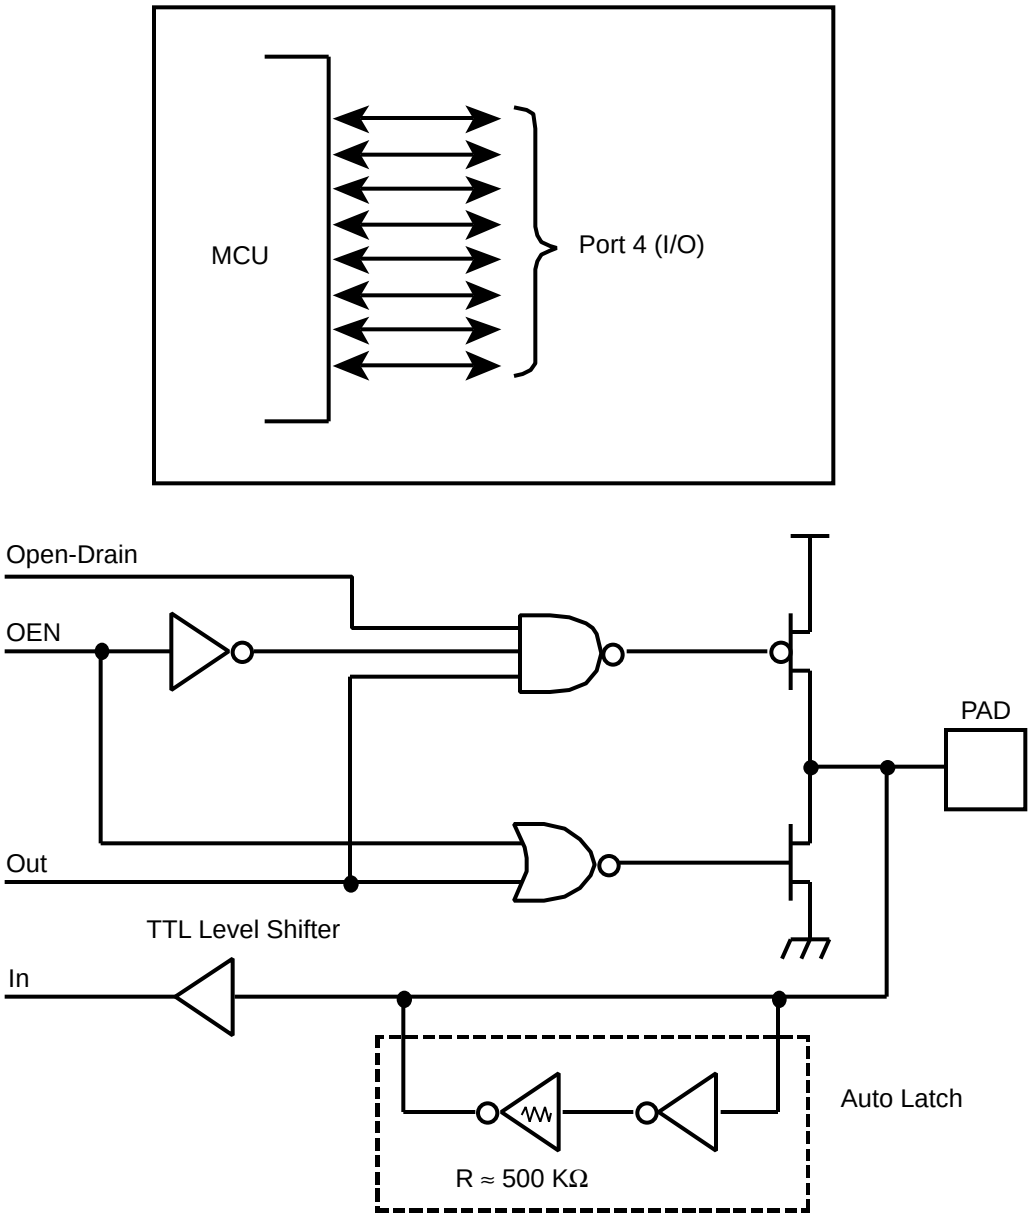

Figure 18. Port 4 Configuration

FUNCTIONAL DESCRIPTION

Address Space

Program Memory. The Z86C61/62 can address up to 48 KB of external program memory (Figure 19). The first 12 bytes of program memory are reserved for the interrupt vectors. These locations contain six 16-bit vectors that correspond to the six available interrupts. For ROM mode, byte 13 to byte 16383 consists of on-chip ROM. At addresses 16384 and greater, the Z86C61/62 executes external program memory fetches. The Z86C96, and the Z86C61/62 in ROMless mode, can address up to 64 KB of external program memory. Program execution begins at external location 000CH after a reset.

Data Memory (/DM). The ROM version can address up to 48 KB of external data memory space beginning at location 16384. The ROMless version can address up to 64 KB of external data memory. External data memory may be included with, or separated from, the external program memory space. /DM, an optional I/O function that can be programmed to appear on pin P34, is used to distinguish between data and program memory space (Figure 20). The state of the /DM signal is controlled by the type instruction being executed. An LDC opcode references PROGRAM (/DM inactive) memory, and an LDE instruction references DATA (/DM active Low) memory.

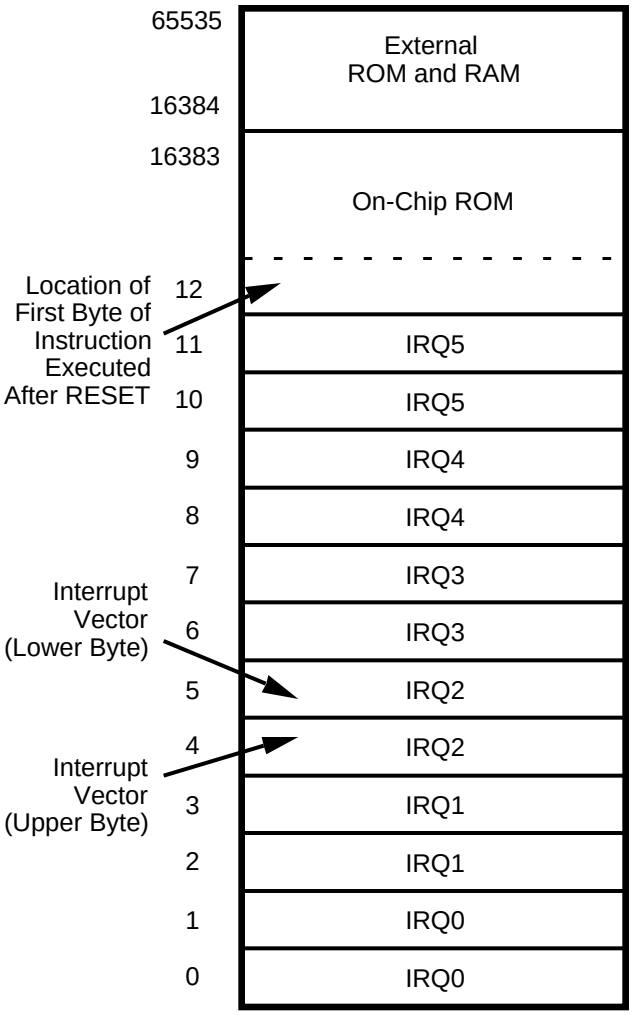

Figure 19. Program Memory Configuration

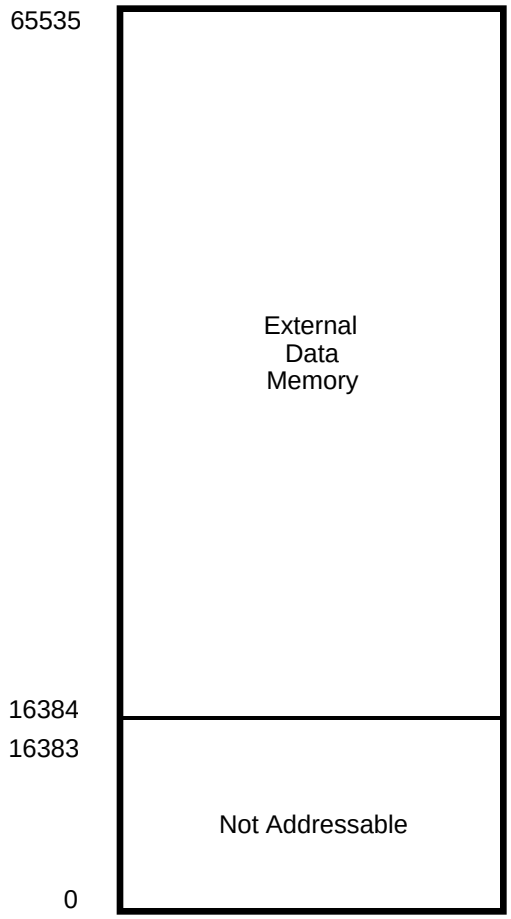

Figure 20. Data Memory Configuration

FUNCTIONAL DESCRIPTION (Continued)

Register File. The Register File consists of four I/O port registers, 236 general-purpose registers and 16 control and status registers (Figure 18). There are eight further registers for I/O ports 4, 5 and 6 in the Expanded Register File (Bank F, R9-R2) (Figure 20).

The instructions can access registers directly or indirectly through an 8-bit address field. The Z86C61/62/96 also allows short 4-bit register addressing using the Register Pointer (Figure 21). In the 4-bit mode, the Register File is divided into 16 working register groups, each occupying 16 continuous locations. The Register Pointer addresses the starting location of the active working-register group.

Note: Register Bank E0-EF can only be accessed through working registers and indirect addressing modes.

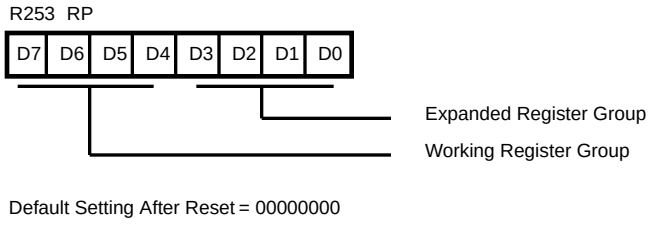

Figure 21. Register Pointer Register

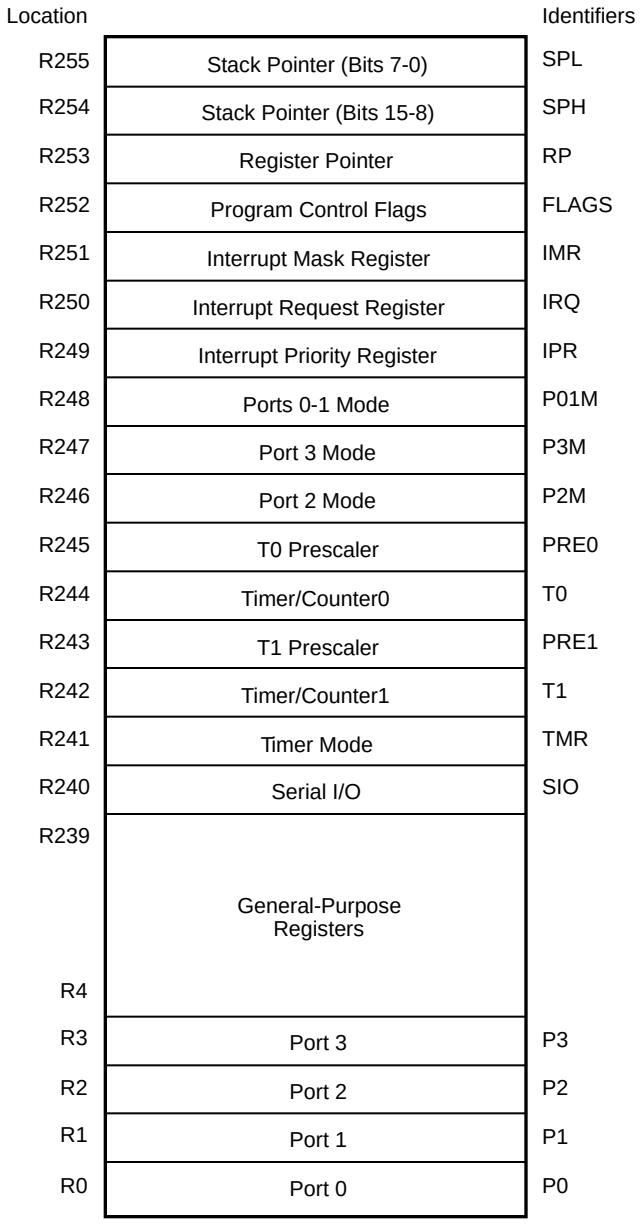

Figure 22. Register File

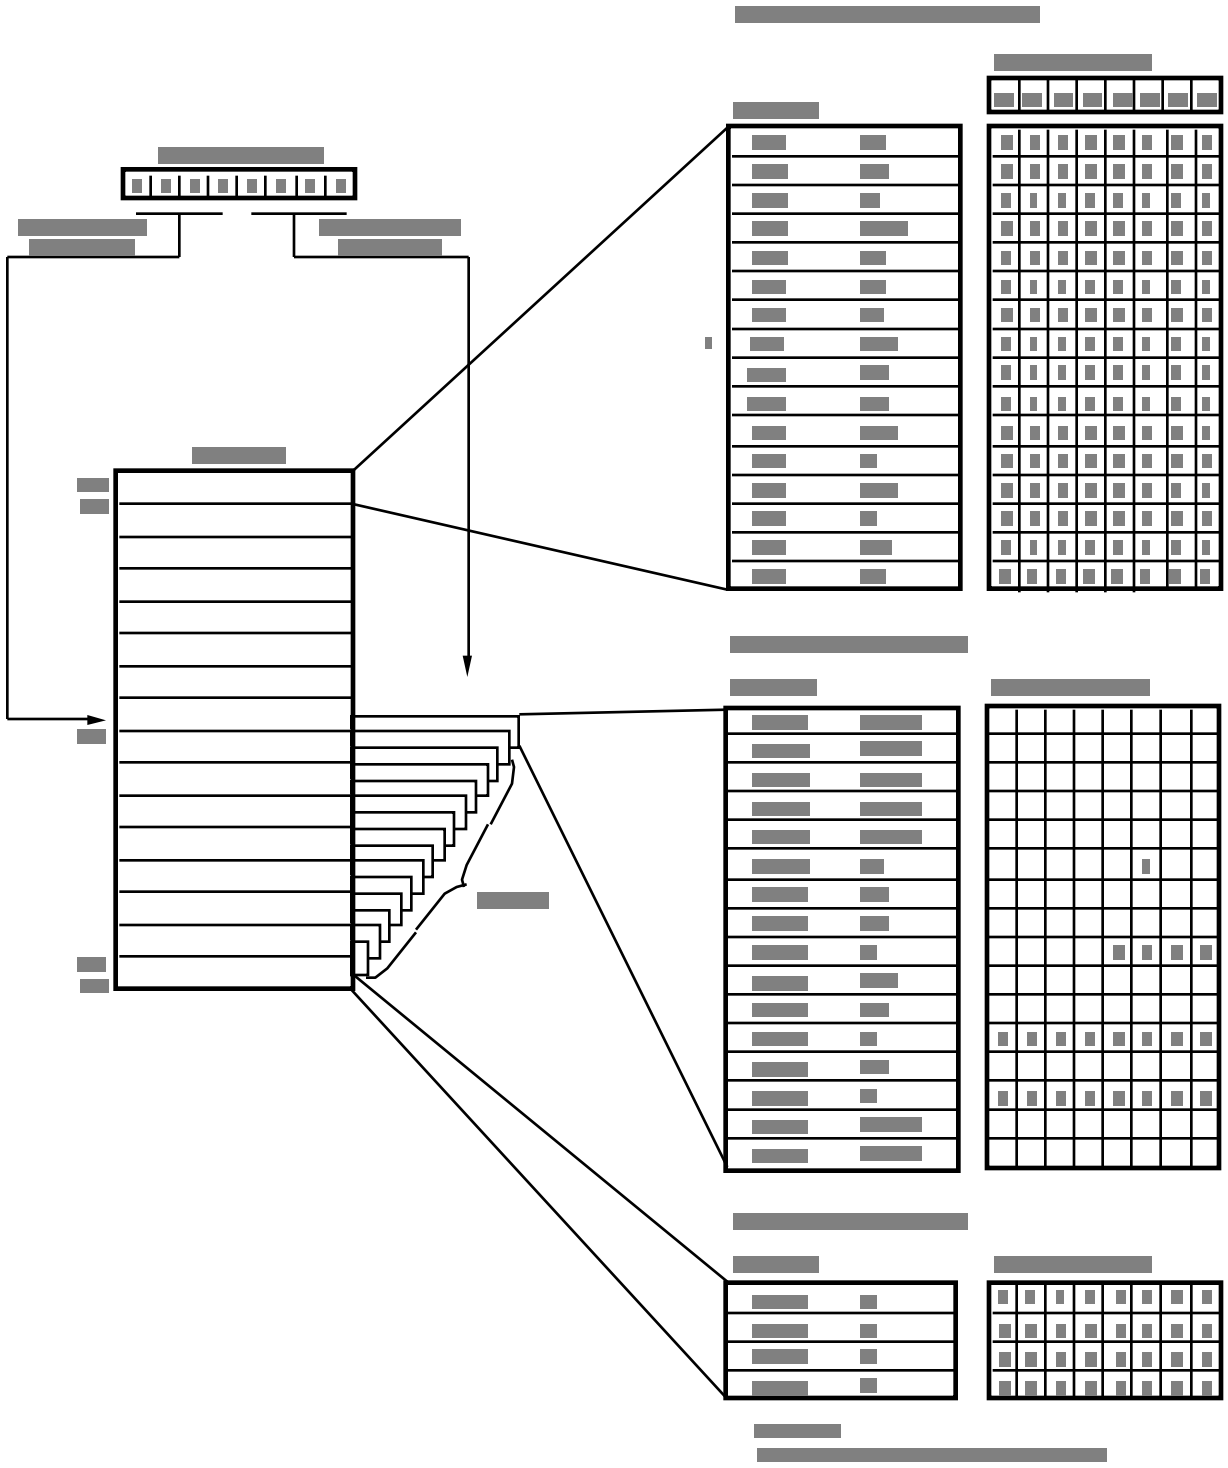

Figure 23. Expanded Register File Architecture

FUNCTIONAL DESCRIPTION (Continued)

Expanded Register File. The register file has been expanded to allow for additional system control registers, and for mapping of additional peripheral devices along with I/O ports into the register address area. The Z8 register address space R0 through R15 has now been implemented as 16 groups of 16 registers per group. These register groups are known as the ERF (Expanded Register File). Bits 7-4 of Register RP select the working register group. Bits 3-0 of Register RP select the expanded register group (Figure 21). Eight I/O port registers reside in the Expanded Register File at Bank F. The rest of the Expanded Register is not physically implemented and is open for future expansion.

The upper nibble of the register pointer (Figure 20) selects which group of 16 bytes in the register file, out of the full 236, will be accessed. The lower nibble selects the expanded register file bank and in the case of the Z86C61/62/96, only Bank F is implemented. A 0H in the lower nibble will allow the normal register file to be addressed, but any other value from 1H to FH will exchange the lower 16 registers in favor of an expanded register group of 16 registers.

For example:

Z86C61: (See Figures 21 and 22)

R253 RP = 00H	R0 = Port 0	R2 = Port 2
	R1 = Port 1	R3 = Port 3

But If:

R253 RP = 0FH
R0 = Reserved
R1 = Reserved
R2 = Port 4
R3 = Port 4, Direction Register
R9 = Port 6, Mode Register

Further examples:

SRP #0FH	Set working group 0 and Bank F
LD R2, #10010110	Load value into Port 4 using working register addressing.
LD 2, #10010110	Load value into Port 4 using absolute addressing.
LD 9, #11110000	Load value into Port 6 mode.
SRP #1FH	Set working group 1 and Bank F
LD R2, #11010110	Load value into general purpose register 12H
LD 12H, #11010110	Load value into general purpose register 12H
LD 2, #10010110	Load value into Port 4

RAM Protect. The upper portion of the RAM's address spaces 80FH to EFH (excluding the control registers) can be protected from reading and writing. The RAM Protect bit option is mask-programmable and is selected by the customer when the ROM code is submitted. After the mask option is selected, the user can activate from the internal ROM code to turn off/on the RAM Protect by loading a bit D6 in the IMR register to either a 0 or a 1, respectively. A 1 in D6 indicates RAM Protect enabled.

ROM Protect. The first 16 Kbytes of program memory is mask programmable. A ROM protect feature prevents "dumping" of the ROM contents by inhibiting execution of LDC, LDCI, LDE, and LDEI instructions by external program memory when pointing to internal memory locations. Therefore these instructions can be used only when they are executed from internal memory, or if they are executed from external memory and pointing to external memory locations.

The ROM Protect option is mask-programmable, to be selected by the customer at the time when the ROM code is submitted.

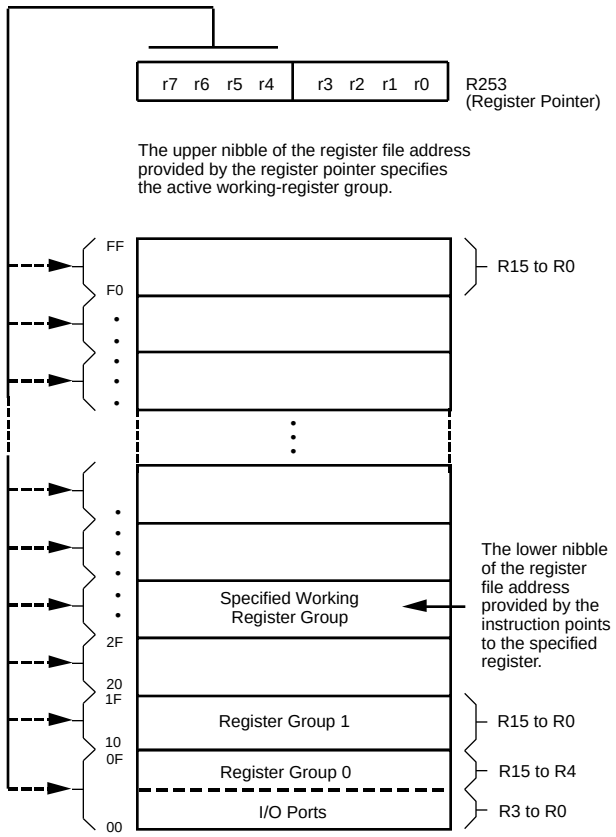

Figure 24. Register Pointer

Stack. The Z86C61/62/96 has a 16-bit Stack Pointer (R255-R254) used for external stack that resides anywhere in the data memory for the ROMless mode, but only from 16384 to 65535 in the ROM mode. An 8-bit Stack Pointer (R255) is used for the internal stack that resides within the 236 general-purpose registers (R239-R4). The high byte of the Stack Pointer (SPH-Bit 8-15) can be used as a general purpose register when using internal stack only.

Counter/Timers. There are two 8-bit programmable counter/timers (T0-T1), each driven by its own 6-bit programmable prescaler. The T1 prescaler can be driven by internal or external clock sources; however, the T0 prescaler is driven by the internal clock only (Figure 22).

The 6-bit prescalers can divide the input frequency of the clock source by any integer number from 1 to 64. Each prescaler drives its counter, which decrements the value (1 to 256) that has been loaded into the counter. When both the counters and prescaler reach the end of the count, a timer interrupt request, IRQ4 (T0) or IRQ5 (T1), is generated.

The counter can be programmed to start, stop, restart to continue, or restart from the initial value. The counters can also be programmed to stop upon reaching zero (single pass mode) or to automatically reload the initial value and continue counting (modulo-n continuous mode).

The counter, but not the prescalers, can be read at any time without disturbing their value or count mode. The clock source for T1 is user-definable and can be either the internal microprocessor clock divided-by-four, or an external signal input through Port 3. The Timer Mode register configures the external timer input (P31) as an external clock, a trigger input that can be retriggerable or non-retriggerable, or as a gate input for the internal clock. Port 3, line P36, also serves as a timer output (TOUT) through which T0, T1 or the internal clock can be output. The counter/timers can be cascaded by connecting the T0 output to the input of T1.

FUNCTIONAL DESCRIPTION (Continued)

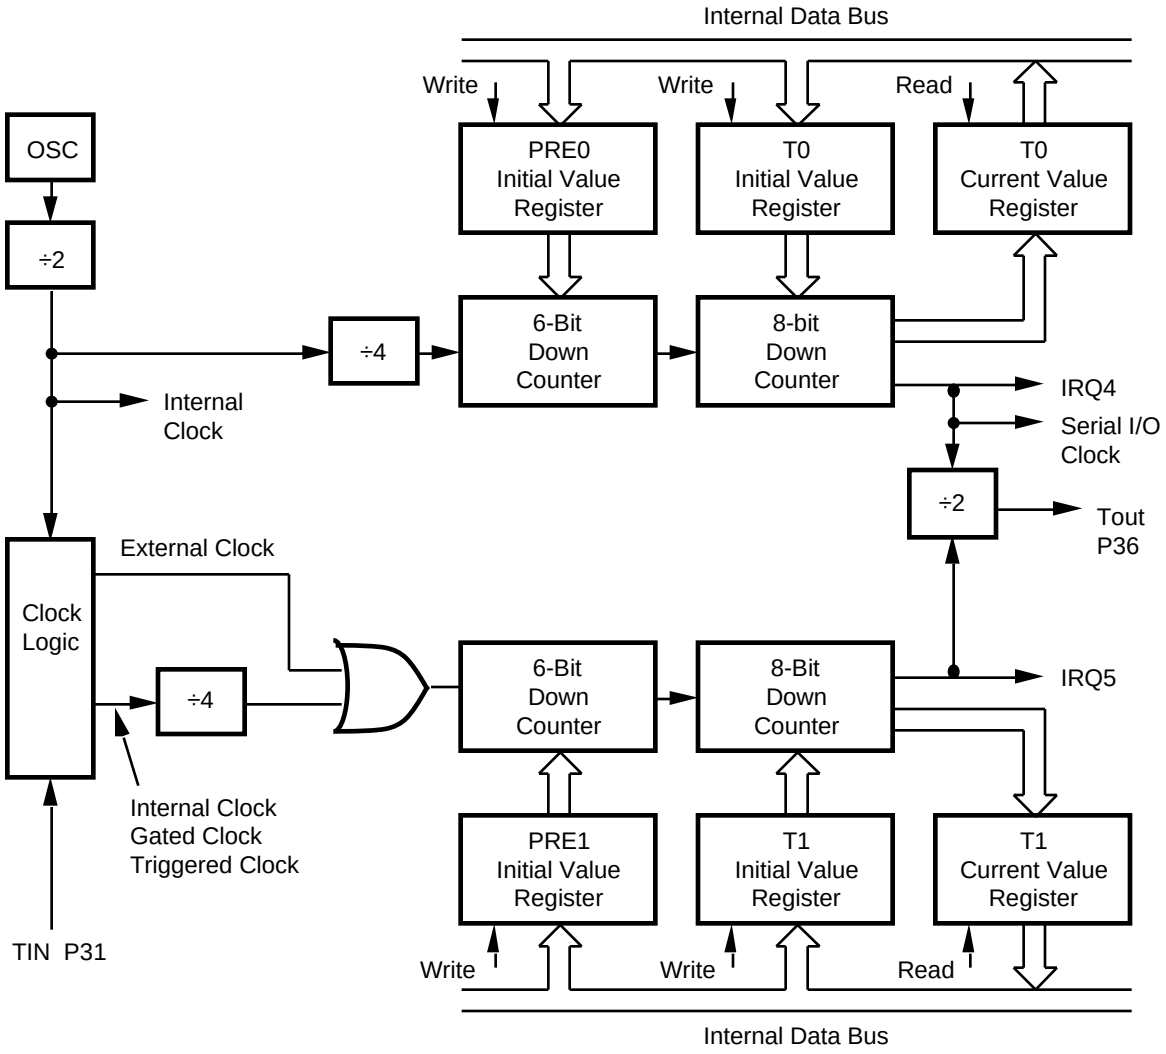

Figure 25. Counter/Timer Block Diagram

Interrupts. The Z86C61/62/96 has six different interrupts from eight different sources. The interrupts are maskable and prioritized. The eight sources are divided as follows: four sources are claimed by Port 3 lines P33-P30, one in Serial Out, one is Serial In, and two in the counter/timers (Figure 26). The Interrupt Mask Register globally or individually enables or disables the six interrupt requests. When more than one interrupt is pending, priorities are resolved by a programmable priority encoder that is controlled by the Interrupt Priority register. All Z86C61/62/96 interrupts are vectored through locations in the program memory. When an interrupt machine cycle is activated, an interrupt request is granted. Thus, this disables all of the subsequent interrupts, saves the Program Counter and Status Flags, and then branches to the program memory vector location reserved for that interrupt. This memory location and the next byte contain the 16-bit address of the interrupt service routine for that particular interrupt request.

To accommodate polled interrupt systems, interrupt inputs are masked and the Interrupt Request register is polled to determine which of the interrupt requests need service. Software initialed interrupts are supported by setting the appropriate bit in the Interrupt Request Register (IRQ).

Internal interrupt requests are sampled on the falling edge of the last cycle of every instruction. The interrupt request must be valid 5TpC before the falling edge of the last clock cycle of the currently executing instruction.

For the ROMless mode, when the device samples a valid interrupt request, the next 48 (external) clock cycles are used to prioritize the interrupt, and push the two PC bytes and the FLAG register onto the stack. The following nine cycles are used to fetch the interrupt vector from external memory. The first byte of the interrupt service routine is fetched beginning on the 58th TpC cycle following the internal sample point, which corresponds to the 63rd TpC cycle following the external interrupt sample point.

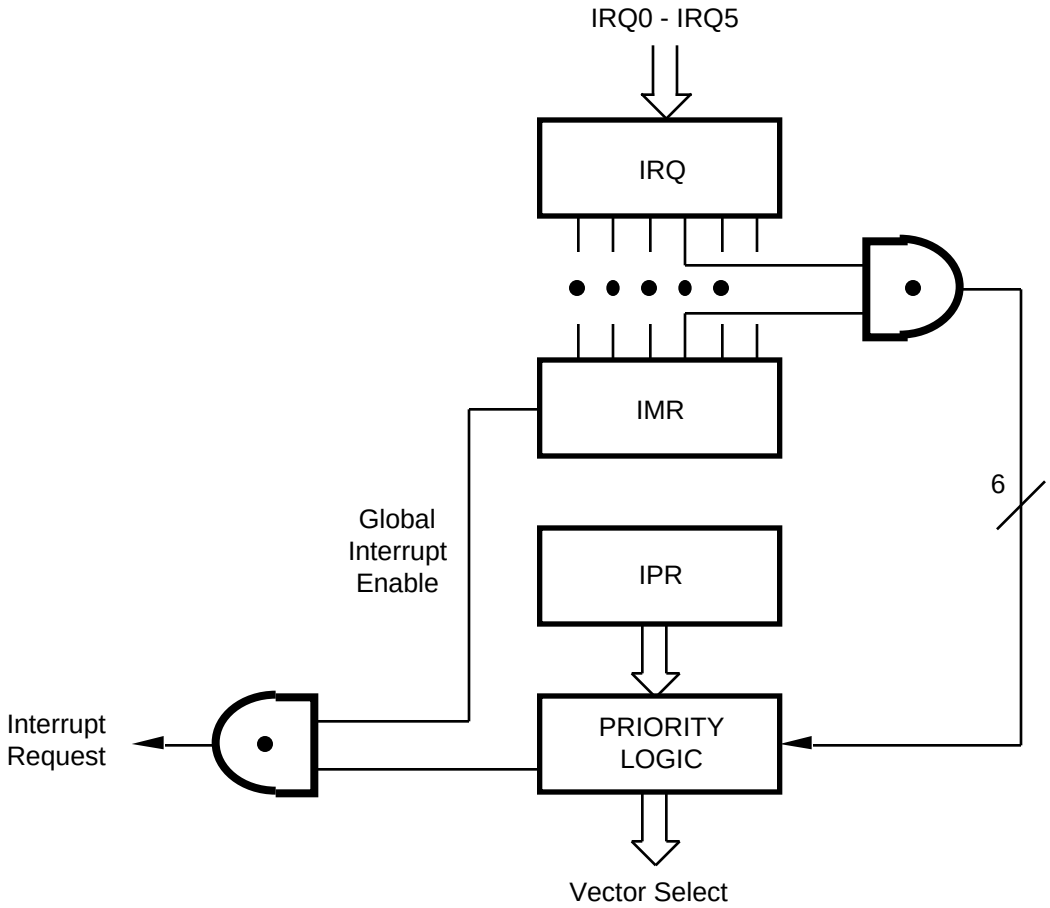

Figure 26. Interrupt Block Diagram

FUNCTIONAL DESCRIPTION (Continued)

Clock. The Z86C61/62/96 on-chip oscillator has a high-gain, parallel-resonant amplifier for connection to a crystal, LC, ceramic resonator, or any suitable external clock source (XTAL1 = Input, XTAL2 = Output). The crystal should be AT cut, 1 MHz to 20 MHz max, and series resistance (RS) is less than or equal to 100 Ohms. The crystal should be connected across XTAL1 and XTAL2 using the recommended capacitors (10 pF < CL < 100 pF) from each pin to device ground (Figure 27).

Note: Actual capacitor values specified by the crystal manufacturer.

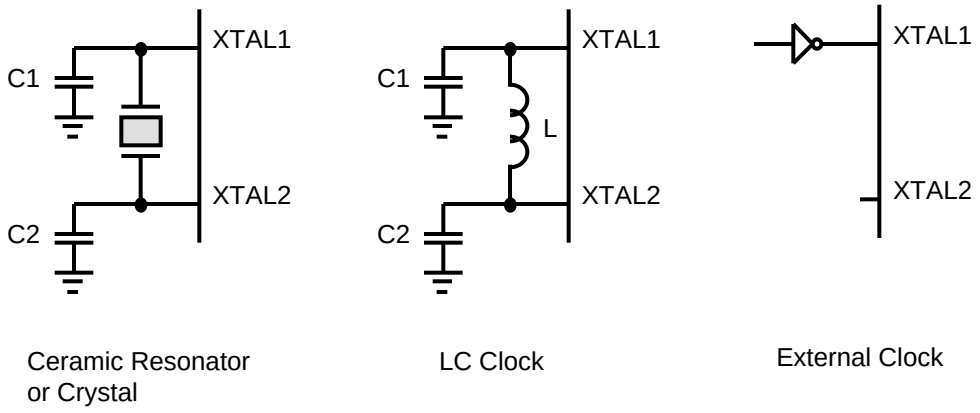

Figure 27. Oscillator Configuration

HALT. Turns off the internal CPU clock but not the XTAL oscillation. The counter/timers and the external interrupts IRQ0, IRQ1, IRQ2, and IRQ3 remain active. The devices are recovered by interrupts, either externally or internally generated. An interrupt request must be executed (enabled) to exit HALT mode. After the interrupt service routine, the program continues from the instruction after the HALT.

STOP. This instruction turns off the internal clock and external crystal oscillation and reduces the standby current to 5 µA (typical) or less. The STOP mode is terminated by a reset, which causes the processor to restart the application program at address 000CH.

In order to enter STOP (or HALT) mode, it is necessary to first flush the instruction pipeline to avoid suspending execution in mid-instruction. To do this, the user must execute a NOP (opcode=0FFH) immediately before the appropriate sleep instruction, i.e.,

```
FF      NOP     ; clear the pipeline
6F      STOP    ; enter STOP mode
                    or
FF      NOP     ; clear the pipeline
7F      HALT    ; enter HALT mode
```
