

General Description

The MIC4834 is a low noise dual Electroluminescent (EL) Panel driver used in backlighting applications. The MIC4834 converts a low DC voltage to a high DC voltage using a boost converter and then alternates the high DC voltage across the EL panels using an H-bridge. The MIC4834 incorporates internal wave-shaping circuitry specifically designed to reduce audible noise emitted by EL panels. With only one inductor the MIC4834 can drive two outputs and requires a minimum number of passive components. It features an operating input voltage range of 2.3V to 5.8V, making it suitable for 1-cell Li-ion and 2- or 3-cell alkaline/NiCad/NiMH battery applications.

The MIC4834 features separate oscillators for the boost and H-bridge stages. The boost frequency may be adjusted with an external resistor to optimize efficiency and brightness. The H-bridge frequency is internally preset to 225Hz, to reduce the number of external components and layout space.

The MIC4834 is available in 10 pin 3mmx3mm MLF[®] package as well as MSOP-10L, and has an operating junction temperature range of -40°C to +125°C.

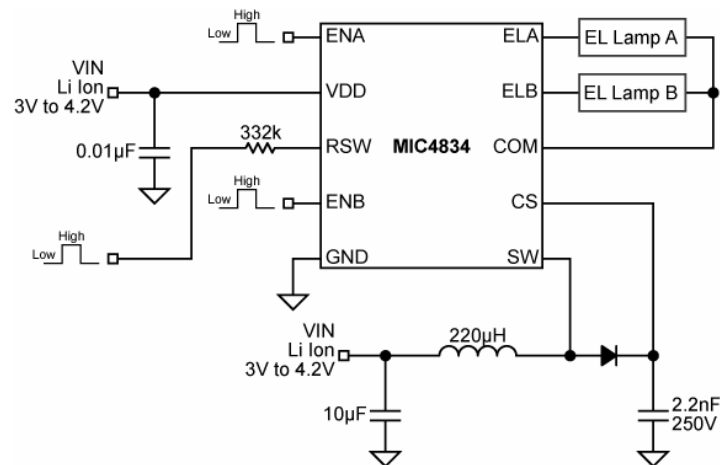

Features

- Drives two EL panels, up to 3 in² each at full brightness
- 220V_{PP} regulated AC output waveform
- 2.3V to 5.8V DC input voltage
- Wave-shaping circuit to reduce audible noise
- Adjustable boost converter frequency
- Single inductor to power both panels
- 0.1μA typical shutdown current
- Package options
 - 10-pin 3mmx3mm MLF[®]
 - 10-pin MSOP
- -40°C to +125°C junction temperature range

Applications

- Mobile phones
- MP3/portable media players (PMP)
- Clocks/ watches
- Remote controls
- Cordless phones
- GPS devices
- PDAs

Typical Application

Low Noise Dual EL Driver

Ordering Information

Part Number	Package	Operating Junction Temp Range	Lead Finish
MIC4834YML	10 pin (3mm x 3mm) MLF®	-40°C to +125°C	Pb-free / RoHS-Compliant
MIC4834YMM	10-Pin MSOP	-40°C to +125°C	Pb-free / RoHS-Compliant

Pin Description

Pin Number	Pin Name	Pin Function
1	ENA	EL Panel A Enable Pin: Logic high enables ELA and logic low disables ELA output.
2	VDD	DC Input Supply Voltage: 2.3V to 5.8V
3	RSW	RSW pin: Sets internal boost converter switch frequency by connecting an external resistor (R_{SW}) to VDD. Connecting the R_{SW} resistor to GND shuts down the device.
4	ENB	EL Panel B enable pin: Logic high enables ELB and logic low disables ELB output.
5	GND	Ground.
6	SW	Switch Node: Drain of internal high-voltage power MOSFET for boost circuit.
7	CS	Regulated Boost Output: Connect to the output capacitor of the boost regulator and to the cathode of the diode.
8	COM	EL output: Common EL output terminal to both ELA and ELB. Connect one end of each EL panel to this pin.
9	ELB	EL Panel B output: Connect the other end of the EL panel B to this pin.
10	ELA	EL Panel A output: Connect the other end of the EL panel A to this pin.
EPad	HS Pad	Heat Sink Pad. Connect to ground externally. MLF® package only.

Absolute Maximum Rating⁽¹⁾

Supply voltage (V_{DD})	-0.5V to 6.5V
Output voltage (V_{CS})	-0.5V to 130V
Switch Node (V_{SW})	-0.5V to 130V
Enable Voltage ($V_{RSW}, V_{ENA}, V_{ENB}$)	-0.5V to 6.5V
Ambient Storage Temperature (T_S)	-65°C to +150°C
ESD Rating ⁽³⁾	ESD Sensitive

Operating Range⁽²⁾

Supply Voltage (V_{DD})	2.3V to 5.8V
Switching MOSFET Frequency (f_{SW})	35kHz to 350kHz
Enable Voltage ($V_{RSW}, V_{ENA}, V_{ENB}$)	0V to V_{DD}
Junction Temperature Range (T_J)	-40°C to +125°C
Package Thermal Impedance	
3mm x 3mm MLF [®] (θ_{JA})	60°C/W
MSOP (θ_{JA})	206°C/W

Figure 1. MIC4834 Block Diagram

Functional Description

Overview

The MIC4834 is a high-voltage dual output EL driver with a peak-to-peak AC output voltage of 220V capable of driving two 3 in² EL panels. The MIC4834 drives EL panels by converting a low DC input voltage to a high DC high output voltage using the boost regulator circuit and then alternating the high DC voltage across the EL panel using an H-Bridge. Input supply current for the MIC4834 is typically 152µA. The high voltage EL driver has two internal oscillators to control the boost switching frequency and the H-bridge driver frequency. The internal boost oscillator frequency can be individually

programmed through an external resistor to maximize efficiency and brightness of the EL panel. The H-bridge frequency is internally fixed at 225Hz to reduce external component count.

Regulation

Referring to Figure 1, power is initially applied to V_{DD}. When the internal feedback voltage is less than the reference voltage, the internal comparator enables switching in the boost circuit. When the boost regulator is switching, current flows through the inductor into the switch. The switching MOSFET will typically turn on for 90% of the switching period. During the on-time, energy

is stored in the inductor. When the switching MOSFET turns off, current flowing into the inductor forces the voltage across the inductor to reverse polarity. The voltage across the inductor rises until the external diode conducts and clamps the voltage at $V_{OUT} + V_{D1}$. The energy in the inductor is then discharged into the C_{OUT} capacitor. The internal comparator continues to turn the switching MOSFET on and off until the internal feedback voltage is above the reference voltage. Once the internal feedback voltage is above the reference voltage, the internal comparator disables switching. The control circuit will continue to turn the MOSFET's on and off to maintain a constant DC voltage at the CS pin.

When the MIC4834 EL Driver is enabled, ELA and ELB will switch in opposite states with COM to achieve a 220V peak-to-peak AC output signal needed to drive the two EL panels.

Switching Frequency

The switching frequency of the converter is controlled by an external resistor (R_{SW}) between RSW and VDD. The switching frequency increases as the resistor value decreases. In general, the lower the switching frequency, the greater the input current is drawn to deliver more power to the output. Lowering the switching frequency can be used to drive larger panels. However, the switching frequency should not be so low as to allow the voltage at the switch node or the CS pin to exceed the absolute maximum voltage of those pins. For resistor value selections, see the "Typical Characteristics: Switching Frequency vs. SW Resistor" graph on Page 4 or use the equation below. The switching frequency range is 35kHz to 350kHz, with an accuracy of $\pm 20\%$.

$$f_{SW} \text{ (kHz)} = \frac{46}{R_{SW} \text{ (M}\Omega\text{)}}$$

EL Frequency

The MIC4834 EL panel frequency is internally fixed at 225Hz.

Enable Function

There are a few different ways to enable and disable the MIC4834. The boost regulator may be disabled by pulling the R_{SW} resistor to ground. This turns off both the EL panels by cutting power to the device completely. The R_{SW} resistor must be pulled to VDD to enable the boost oscillator. If it is not equal to VDD, then the frequency set by R_{SW} will be different the programmed value.

For individual panel control, the ENA and ENB pins can be used to enable ELA and ELB, respectively. Pulling

ENA or ENB high (over 1.2V) or low (below 0.4V) will turn ELA and ELB panels on or off.

Application Information

The MIC4834 is designed to use an inductance with a value between 100 μ H to 330 μ H. Choosing the right inductor is always a balance of size, inductance, efficiency, current rating and cost. A TDK (VLS4012T-221M) 220 μ H inductor is recommended based on size, efficiency and current rating.

Generally, the lower the inductance, the more current the inductor can handle. Lowering the inductance allows the boost regulator to draw more input current to deliver more energy every switching cycle. As a result, a lower inductance may be used to drive larger panels or brighten similar sized panels. However, caution is required as using a low inductance with a low switching frequency may cause the voltage at the switch node and the CS pin to exceed the absolute maximum rating. If the application uses a low input voltage (2.3V to 3V), then a lower value inductor, such as 100 μ H, may be used in order to drive the EL panel at maximum brightness.

Diode

The diode must have a high reverse voltage (150V), since the output voltage at the CS pin can reach up to 130V. A fast switching diode with lower forward voltage and higher reverse voltage (150V), such as BAV20WS/BAS20W, can be used to enhance efficiency.

Output Capacitor

Low ESR capacitors should be used at the regulated boost output (CS pin), to minimize the switching output ripple voltage. The larger the output capacitance, the lower the output ripple at the CS pin. The reduced output ripple, at the CS pin, along with a low ESR capacitor improves the efficiency of the MIC4834 circuit. Selection of the capacitor value depends upon the peak inductor current, inductor size, and the load. The MIC4834 is designed for use with an output capacitance as low as 2.2nF. For minimum audible noise, the use of a C0G/NPO dielectric output capacitor is recommended. TDK and AVX offer C0G/NPO dielectric capacitors in capacitance up to 2.7nF at 200V to 250V voltage rating in 0805 size.

EL Panel Terminals (ELA, ELB, COM)

The two EL panels are connected from ELA to COM and ELB to COM. The ELA and ELB terminals are in phase with each other, while the COM is out of phase with both ELA and ELB. Since ELA and COM are out of phase, the high voltage generated by the boost regulator is alternated across ELA and COM by the H-Bridge. The frequency of each cycle is internally fixed at 225Hz. The alternating 220V peak-to-peak causes the EL panel to emit light. Similarly, the ELB and COM are also out of phase and allows a second EL panel to be driven at the same time. Both EL panels may operate independently from each other and do not have to be the same size. For component selection, Table 2 lists recommended values for various panel sizes up to a total of 6 in² (For example, two 3 in² panels). Driving overly large panels will result in a dimmer display, but will not cause damage to the device.

Application Circuit
