

Spread Spectrum Clock Generator

Features

- 25 MHz to 100 MHz operating frequency range
- Nine different spread select options
- Accepts clock and crystal inputs
- Low power dissipation:
 - 56 mW at Fin = 25 MHz
 - 89 mW at Fin = 65 MHz
 - 139 mW at Fin = 100 MHz
- Frequency spread disable function
- Center spread modulation
- Low cycle-to-cycle jitter
- 8-pin SOIC package
- Commercial and industrial temperature ranges

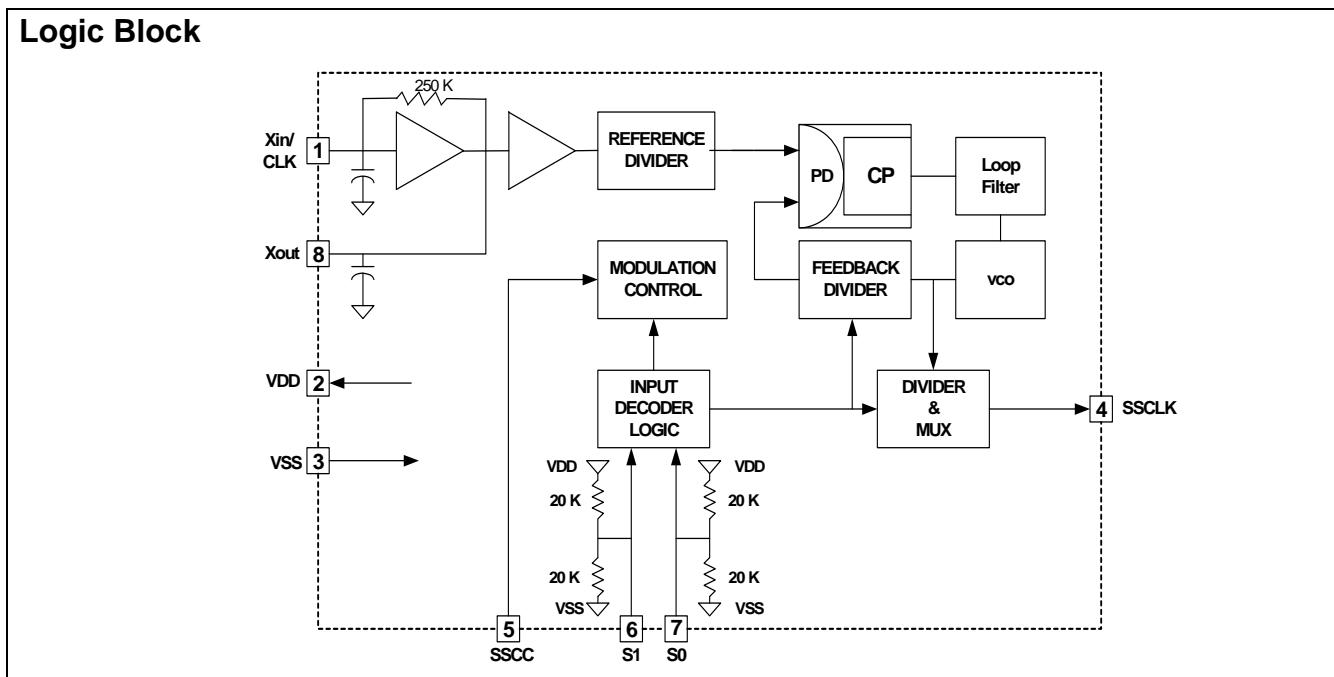

Applications

- Desktop, notebook, and tablet PCs
- VGA controllers
- LCD panels and monitors
- Printers and multifunction devices (MFP)

Benefits

- Peak electromagnetic interference (EMI) reduction by 8 to 16 dB
- Fast time to market
- Cost reduction

Figure 1. Pin Configuration – 8-Pin SOIC Package

Table 1. Pin Description

Pin Number	Pin Name	Type	Pin Description
1	Xin/CLK	I	Clock or crystal connection input. See the Table 2 on page 4 for input frequency range selection.
2	VDD	P	Positive power supply.
3	GND	P	Power supply ground.
4	SSCLK	O	Modulated clock output, that is the same frequency as the input clock or the crystal frequency.
5	SSCC	I	Spread spectrum clock control (enable/disable) function. SSCG function is enabled when input is high and disabled when input is low. This pin is pulled high internally.
6	S1	I	Tri-level logic input control pin used to select input frequency range and spread percent. See the “ Tri-Level Logic ” on page 4 for programming details. Pin 6 has an internal resistor divider network to V_{DD} and V_{SS} . See the Logic Block Diagram on page 1 .
7	S0	I	Tri-level logic input control pin used to select input frequency range and spread percent. See the “ Tri-Level Logic ” on page 4 for programming details. Pin 7 has an internal resistor divider network to V_{DD} and V_{SS} . See the Logic Block Diagram on page 1 .
8	Xout	O	Oscillator output pin connected to crystal. Leave this pin unconnected if an external clock is used to drive xin/clk input (Pin 1).

General Description

The Cypress CY25560 is a spread spectrum clock generator (SSCG) IC used to reduce the EMI found in today’s high-speed digital electronic systems.

The CY25560 uses Cypress’s proprietary phase-locked loop (PLL) and spread spectrum clock (SSC) technology to synthesize and frequency modulate the input frequency of the reference clock. By frequency modulating the clock, the measured EMI at the fundamental and harmonic frequencies of clock (SSCLK) is greatly reduced.

This reduction in radiated energy can significantly reduce the cost of complying with regulatory requirements and time to market without degrading system performance.

The CY25560 is a very simple and versatile device to use. The frequency and spread% range is selected by programming S0 and S1 digital inputs. These inputs use three (3) logic states including High (H), Low (L), and Middle (M) logic levels to select one of the nine available spread% ranges. See the [Table 2 on page 4](#) for programming details.

CY25560 is optimized for SVGA (40 MHz) and XVGA (65 MHz) controller clocks and also suitable for applications where the frequency range is 25 MHz to 100 MHz.

A wide range of digitally selectable spread percentages is made possible by using three-level (High, Low, and Middle) logic at the S0 and S1 digital control inputs.

The output spread (frequency modulation) is symmetrically centered on the input frequency.

Spread spectrum clock control (SSCC) function enables or disables the frequency spread and is provided for easy comparison of system performance during EMI testing.

The CY25560 is available in an 8-pin SOIC package with 0 °C to 70 °C Commercial and –40 °C to 85 °C Industrial operating temperature ranges.

Figure 2. Three-Level Logic Examples

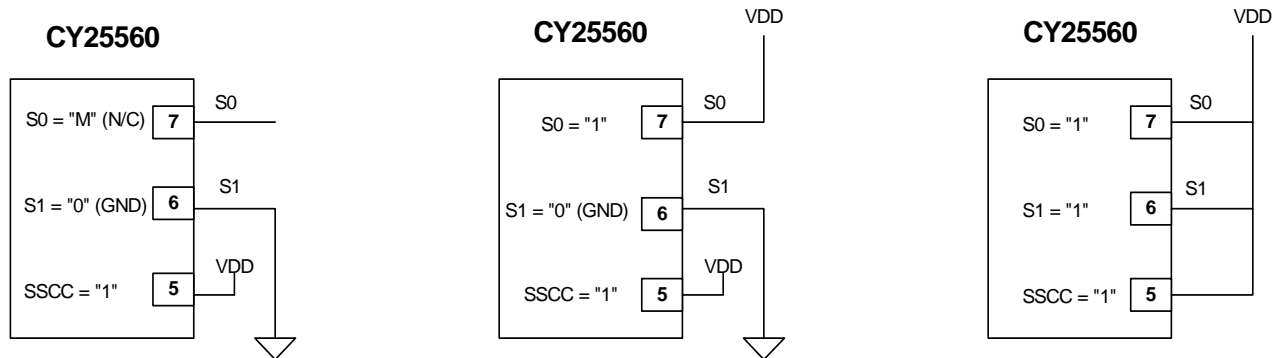

Table 2. Frequency and Spread% Selection

25 – 50 MHz (Low Range)

Input Frequency (MHz)	S1=M S0=M (%)	S1=M S0=0 (%)	S1=1 S0=0 (%)	S1=0 S0=0 (%)	S1=0 S0=M (%)
25 – 35	4.3	3.8	3.4	2.9	2.8
35 – 40	3.9	3.5	3.1	2.5	2.4
40 – 45	3.7	3.3	2.8	2.4	2.3
45 – 50	3.4	3.1	2.6	2.2	2.1

Select the Frequency and Center Spread % desired and then set S1, S0 as indicated.

50 – 100 MHz (High Range)

Input Frequency (MHz)	S1=1 S0=M (%)	S1=0 S0=1 (%)	S1=1 S0=1 (%)	S1=M S0=1 (%)
50 – 60	2.9	2.1	1.5	1.2
60 – 70	2.8	2.0	1.4	1.1
70 – 80	2.6	1.8	1.3	1.1
80 – 100	2.4	1.7	1.2	1.0

Select the Frequency and Center Spread % desired and then set S1, S0 as indicated.

Tri-Level Logic

With binary logic, four states can be programmed with two control lines, whereas three-level logic can program nine logic states using two control lines. Three-level logic in the CY25560 is implemented by defining a third logic state in addition to the standard logic '1' and '0'. Pins 6 and 7 of the CY25560 recognize a logic state by the voltage applied to their respective pin. These states are defined as '0' (Low), 'M' (Middle), and '1' (One). Each of these states have a defined voltage range that is interpreted by the CY25560 as a '0', 'M', or '1' logic state. See the Table 3 for voltage ranges for each logic state. The CY25560 has two equal value resistor dividers connected internally to Pins 6 and 7 that produce the default 'M' (Middle) state if these pins are left unconnected (NC). Pins 6 and/or 7 can be tied directly to ground or V_{DD} to program a logic '0' or '1' state, respectively.

SSCG Theory of Operation

The CY25560 is a PLL-type clock generator using a proprietary Cypress design. By precisely controlling the bandwidth of the output clock, the CY25560 becomes a low-EMI clock generator.

The theory and detailed operation of the CY25560 is discussed in the following sections.

EMI

All digital clocks generate unwanted energy in their harmonics. Conventional digital clocks are square waves with a duty cycle that is very close to 50 percent. Because of this 50/50 duty cycle, digital clocks generate most of their harmonic energy in the odd harmonics, i.e., third, fifth, seventh, and so on. It is possible to reduce the amount of energy contained in the fundamental and odd harmonics by increasing the bandwidth of the fundamental clock frequency. Conventional digital clocks have a very high Q factor, that means that all of the energy at that frequency is concentrated in a very narrow bandwidth, consequently, higher energy peaks. Regulatory agencies test electronic equipment by the amount of peak energy radiated from the equipment. By reducing the peak energy at the fundamental and harmonic frequencies, the equipment under test is able to satisfy agency requirements for EMI. Conventional methods of reducing EMI have been to use shielding, filtering, multilayer PCBs, and so on. The CY25560 uses the approach of reducing the peak energy in the clock by increasing the clock bandwidth, and lowering the Q factor.

SSCG

SSCG uses a patented technology of modulating the clock over a very narrow bandwidth and controlled rate of change, both peak and cycle-to-cycle. The CY25560 takes a narrow band digital reference clock in the range of 25 to 100 MHz and produces a clock that sweeps between a controlled start and stop frequency and precise rate of change. To understand what happens to a clock when SSCG is applied, consider a 65 MHz clock with a 50 percent duty cycle. From a 65 MHz clock we know the following:

If this clock is applied to the Xin/CLK pin of CY25560, the output clock at Pin 4 (SSCLK) sweeps back and forth between two frequencies. These two frequencies, F1 and F2, are used to calculate to total amount of spread or bandwidth applied to the reference clock at Pin 1. As the clock is making the transition from F1 to F2, the amount of time and sweep waveform play a very important role in the amount of EMI reduction realized from an SSCG clock.

The modulation domain analyzer is used to visualize the sweep waveform and sweep period. Figure 3 shows the modulation profile of a 65 MHz SSCG clock. Notice that the actual sweep waveform is not a simple sine or sawtooth waveform. Figure 3 also shows a scan of the same SSCG clock using a spectrum analyzer. In this scan you can see a 6.48 dB reduction in the peak RF energy when using the SSCG clock.

Modulation Rate

SSCGs utilize frequency modulation (FM) to distribute energy over a specific band of frequencies. The maximum frequency of the clock (Fmax) and minimum frequency of the clock (Fmin) determine this band of frequencies. The time required to transition from Fmin to Fmax and back to Fmin is the period of the Modulation Rate, Tmod. Modulation Rates of SSCG clocks are generally referred to in terms of frequency or Fmod = 1/Tmod.

The input clock frequency, Fin, and the internal divider count, Cdiv, determine the Modulation Rate. In some SSCG clock generators, the selected range determines the internal divider count. In other SSCG clocks, the internal divider count is fixed over the operating range of the device. The CY25560 has a fixed divider count of 1166.

Figure 3. SSCG Clock, CY25560, Fin = 65 MHz

Device	Divider Count (Cdiv)
CY25560	1166 (All Ranges)

Example:

Device =	CY25560
Fin =	65 MHz
Range =	S1 = 1, S0 = 0

Then:

Modulation Rate = Fmod = 65 MHz/1166 = 55.7 kHz.

Modulation Profile

Spectrum Analyzer

CY25560 Application Schematic

The schematic in Figure 4 demonstrates how the CY25560 is configured in a typical application. This application is shown as using a 30 MHz fundamental crystal. In most applications, an external reference clock is used. Apply the external clock signal at Xin (Pin 1) and leave Xout (Pin 8) unconnected (see Table 1 for pin descriptions).

Contact Cypress if higher order crystal is to be used.
